Consider a sequence of  $k$  positive integers  $\{a_i\}_{i=1}^k$  with the following properties: (i)  $a_i \leq k$  for  $i = 1, \dots, k$ ; (ii) there is an  $n$  such that  $a_i$  is the quotient when  $n+i$  is divided by all its prime factors greater than  $k$  (in other words: for each prime  $p \leq k$ , the pattern of that prime and its powers in the sequence  $a_1, \dots, a_k$  is the same as the pattern of that prime and its powers in some sequence of  $k$  consecutive integers).

Example: the sequence 1, 4, 3, 2, 5 satisfies (i) and (ii) since 91, 92, 93, 94, 95 factor into  $1 \cdot 7 \cdot 13$ ,  $4 \cdot 23$ ,  $3 \cdot 31$ ,  $2 \cdot 47$ ,  $5 \cdot 19$ .

This long but captivating paper starts with a proof that any sequence which satisfies (i) and (ii) is a permutation of  $1, 2, \dots, k$ . However, only very few of the  $k!$  possible permutations can actually occur in such sequences. Six different types of solutions are characterized, and it is proved - the main result of the paper - that these indeed are the only possible patterns which can occur in sequences which obey (i) and (ii). From this, all the solutions for  $k \leq 27$  are derived and listed.

Next, for given  $k$ , the number of possible sequences satisfying (i) and (ii) is studied. It is proved that the logarithmic density of those values of  $k$  with exactly two solutions is positive. Finally, these results are applied to the problem of estimating the least prime factor of binomial coefficients.
