In this note, we give an example of a flat manifold having a trivial group of affinities by constructing a Bieberbach group with a trivial center and trivial outer automorphism group.

#### 1. INTRODUCTION

The compact, connected, flat Riemannian manifolds (flat manifolds for short) are classified up to affine equivalence by their fundamental groups, the so-called Bieberbach groups. These groups are precisely the torsion-free groups satisfying an exact sequence

$$0 \longrightarrow L \longrightarrow \Gamma \longrightarrow G \longrightarrow 1 \tag{1-1}$$

where G is a finite group and L is a faithful  $\mathbb{Z}G$ -lattice of finite rank, i.e., a free  $\mathbb{Z}$ -module of finite rank on which Gacts faithfully. Let X be a flat manifold with fundamental group  $\Gamma$ . The group Aff(X) of affine self-equivalences of X is a Lie group. Its identity component  $Aff_0(X)$  is a torus whose dimension is the rank of the center of  $\Gamma$ , and  $Aff(X)/Aff_0(X)$  is isomorphic to  $Out(\Gamma)$ , the outer automorphism group of  $\Gamma$ . Malfait conjectured [Malfait 98, Conjecture 5.13, that Aff(X) is never torsion-free (where the trivial group is considered to be torsion-free). In Section 2, we will give an example of a Bieberbach group that has a trivial center and trivial outer automorphism group, and hence is the fundamental group of a flat manifold with trivial group of affinities. In particular, it is a counterexample to Malfait's conjecture. Let  $\Gamma$  be a Bieberbach group as in (1-1) and  $\delta \in H^2(G,L)$ be the cohomology class giving rise to (1-1). Let N be the normalizer of G in Aut(L). There is a natural action of N on  $H^2(G, L)$ , and  $Out(\Gamma)$  satisfies the short exact sequence (see [Charlap 86, Theorem V.1.1])

$$0 \longrightarrow H^1(G, L) \longrightarrow \operatorname{Out}(\Gamma) \longrightarrow N_{\delta}/G \longrightarrow 1, \quad (1-2)$$

where  $N_{\delta}$  denotes the stabilizer of  $\delta$  in N. The center of  $\Gamma$  is  $L^G = \{v \in L \mid gv = v \ \forall g \in G\}$ , so to find a flat manifold with no symmetries, it suffices to construct a

torsion-free extension (1–1) such that  $L^G$ ,  $H^1(G,L)$ , and  $N_\delta/G$  are trivial. To do this, we need to know when an extension (1–1) is torsion-free, and this happens if and only if we have  $\operatorname{res}_U^G(\delta) \neq 0$  for all nontrivial subgroups U of G, where  $\operatorname{res}_U^G: H^2(G,L) \to H^2(U,L)$  denotes the restriction homomorphism (see [Charlap 86, Theorem III.2.1]). An element  $\delta \in H^2(G,L)$  satisfying this condition is called special. By transitivity of restriction, it suffices to check this for subgroups of prime order, and by the action of G on  $H^2(G,L)$ , it suffices to consider representatives of conjugacy classes of subgroups. Also, for a Sylow p-subgroup U of G, the restriction homomorphism  $\operatorname{res}_U^G: H^2(G,L)_p \to H^2(U,L)$  is injective. Since it is difficult to compute  $H^2(G,L)$ , we use the isomorphic group  $H^1(G,\mathbb{Q}\otimes_{\mathbb{Z}} L/L)$  instead.

# 2. THE EXAMPLE

Let  $G = M_{11}$ , the Mathieu group on 11 letters. Then G has a presentation

$$\begin{split} G \cong \langle a, b \, | \, a^2, b^4, & (ab)^{11}, (ab^2)^6, \\ & ababab^{-1}abab^2ab^{-1}abab^{-1}ab^{-1} \rangle, \end{split}$$

and representatives of conjugacy classes of subgroups of order 2, respectively, 3 are  $\langle a \rangle$ , respectively,  $\langle (ab^2)^2 \rangle$ ; see [Wilson et al. 01]. Let  $L_1$  be the 20-dimensional integral representation of G from the Web-Atlas [Wilson et al. 01], let  $L_3$  be the dual of the 44-dimensional integral representation of G from the Web-Atlas, and let  $L_2$  and  $L_4$  be the lattices given in Figure 1 and Figure 2, respectively. The lattices are given by the images of the generators a and b under the corresponding integral representation of G, i.e., the lattice is identified with  $\mathbb{Z}^n$  on which G acts by matrix multiplication. Furthermore, let  $\delta_i \in H^1(G, \mathbb{Q} \otimes_{\mathbb{Z}} L_i/L_i)$  for  $1 \leq i \leq 4$  be the cocycles given in Figure 3. A cocycle  $\delta$  is given by vectors  $v_a, v_b \in \mathbb{Q}^n$  such that  $\delta(a) = v_a + \mathbb{Z}^n$  and  $\delta(b) = v_b + \mathbb{Z}^n$ . These have the following properties:

- (1) The character afforded by  $L_1$  is  $\chi + \bar{\chi}$ , where  $\chi$  is one of the two nonreal irreducible characters of G of degree 10. The order of  $\delta_1$  is 6, and we have  $\operatorname{res}_{\langle a \rangle}^G(\delta_1) = 0$ , but  $\operatorname{res}_{\langle (ab^2)^2 \rangle}^G(\delta_1) \neq 0$ .
- (2) The character afforded by  $L_2$  is  $\chi + \bar{\chi}$ , where  $\chi$  is one of the two irreducible characters of G of degree 16. The order of  $\delta_2$  is 5. Hence the restriction of  $\delta_2$  to any subgroup of order 5 is nonzero.
- (3) The character afforded by  $L_3$  is the irreducible character of G of degree 44. The order of  $\delta_3$  is 6, and we have  $\operatorname{res}_{\langle a \rangle}^G(\delta_3) \neq 0$ , but  $\operatorname{res}_{\langle (ab^2)^2 \rangle}^G(\delta_3) = 0$ .

(4) The character afforded by  $L_4$  is the irreducible character of G of degree 45. The order of  $\delta_4$  is 11. Hence the restriction of  $\delta_4$  to any subgroup of order 11 is nonzero.

Thus  $\delta := \delta_1 + \cdots + \delta_4 \in H^1(G, \mathbb{Q} \otimes_{\mathbb{Z}} L/L)$ , where  $L := L_1 \oplus \cdots \oplus L_4$ , is a special element. Let  $\Gamma$  be an extension of L by G given by  $\delta$ . Then  $\Gamma$  is torsion-free and has trivial center. Moreover, we have  $H^1(G, L) = 0$ . This is easily checked using the fact that, if  $L^G = 0$ , a prime p divides  $|H^1(G,L)|$  if and only if  $(L/pL)^G \neq 0$  (see [Hiss and Szczepański 97, Lemma 2.1]). Now it remains to check that  $N_{\text{Aut}(L)}(G)_{\delta} = G$ . Since G has no outer automorphisms, we have  $N_{\text{Aut}(L)}(G) = C_{\text{Aut}(L)}(G)G$ , and the centralizer of G in  $\operatorname{Aut}(L)$  is  $C_{\operatorname{Aut}(L_1)}(G) \times \cdots \times$  $C_{\mathrm{Aut}(L_4)}(G)$ . We claim that  $C_{\mathrm{Aut}(L_i)}(G) = \{\pm 1\}$  for  $1 \leq i \leq 4$ . This is obvious for i = 3, 4. Now  $C_{\operatorname{Aut}(L_i)}(G)$ is the unit group of  $\operatorname{End}_{\mathbb{Z}G}(L_i)$ , which is a  $\mathbb{Z}$ -order in  $\operatorname{End}_{\mathbb{O}G}(\mathbb{O}\otimes_{\mathbb{Z}} L_i)$ . For i=1,2, this endomorphism ring is isomorphic to  $\mathbb{Q}(\chi)$ , where  $\chi$  is as above. In the first case,  $\mathbb{Q}(\chi) = \mathbb{Q}(\sqrt{-2})$ , and in the second case, we have  $\mathbb{Q}(\chi) = \mathbb{Q}(\sqrt{-11})$ . In both cases, all  $\mathbb{Z}$ -orders have unit group  $\{\pm 1\}$ , hence the claim. Now it is clear that  $C_{\mathrm{Aut}(L)}(G)_{\delta}=1$  and we are done.

The computations in this example have been performed with GAP [GAP 02] and CARAT [Opgenorth et al. 01].

It would be desirable to have more than one example, preferably an infinite family. But to achieve this using the above strategy, one needs a family of lattices with the "right" properties, and I do not know of such a family.

# **ACKNOWLEDGMENTS**

This example is the main result of my diploma thesis and I am grateful to my advisor G. Hiss for helpful hints and his encouragement to publish it. Also, I would like to thank J. Müller for several discussions.
