It is shown that the sequence obtained by reducing modulo  $m$  coefficient and exponent of each Fibonacci polynomials term is periodic. Also if  $p$  is prime, then sequences of Fibonacci polynomial are compared with Wall numbers of Fibonacci sequences according to modulo  $p$ . It is found that order of cyclic group generated with  $Q_2$  matrix  $\begin{pmatrix} x & 1 \\ 1 & 0 \end{pmatrix}$  is equal to the period of these sequences.

## 1. Introduction

In modern science there is a huge interest in the theory and application of the Fibonacci numbers. The Fibonacci numbers  $F_n$  are the terms of the sequence  $0, 1, 1, 2, 3, 5, \dots$ , where  $F_n = F_{n-1} + F_{n-2}$ ,  $n \geq 2$ , with the initial values  $F_0 = 0$  and  $F_1 = 1$ . Generalized Fibonacci sequences have been intensively studied for many years and have become an interesting topic in Applied Mathematics. Fibonacci sequences and their related higher-order sequences are generally studied as sequence of integer. Polynomials can also be defined by Fibonacci-like recurrence relations. Such polynomials, called Fibonacci polynomials, were studied in 1883 by the Belgian mathematician Eugene Charles Catalan and the German mathematician E. Jacobsthal. The polynomials  $F_n(x)$  studied by Catalan are defined by the recurrence relation

$$F_n(x) = xF_{n-1}(x) + F_{n-2}(x), \quad n \geq 3, \quad (1)$$

where  $F_1(x) = 1, F_2(x) = x$ . The Fibonacci polynomials studied by Jacobsthal are defined by

$$J_n(x) = J_{n-1}(x) + xJ_{n-2}(x), \quad n \geq 3, \quad (2)$$

where  $J_1(x) = J_2(x) = 1$ . The Fibonacci polynomials studied by P. F. Byrd are defined by

$$\varphi_n(x) = 2x\varphi_{n-1}(x) + \varphi_{n-2}(x), \quad n \geq 2, \quad (3)$$

where  $\varphi_0(x) = 0, \varphi_1(x) = 1$ . The Lucas polynomials  $L_n(x)$ , originally studied in 1970 by Bicknell and they are defined by

$$L_n(x) = xL_{n-1}(x) + L_{n-2}(x), \quad n \geq 2, \quad (4)$$

where  $L_0(x) = 2, L_1(x) = x$  [1].

Hoggatt and Bicknell introduced a generalized Fibonacci polynomials and their relationship to diagonals of Pascal's triangle [2]. Also after investigating the generalized  $Q$ -matrix, Ivie introduced a special case [3]. Nalli and Haukkanen introduced  $h(x)$ -Fibonacci polynomials that generalize both Catalan's Fibonacci polynomials and Byrd's Fibonacci Polynomials and the  $k$ -Fibonacci number. Also they provided properties for these  $h(x)$ -Fibonacci polynomials where  $h(x)$  is a polynomial with real coefficients [1].

*Definition 1.* The Fibonacci polynomials are defined by the recurrence relation

$$F_n(x) = \begin{cases} 0, & \text{if } n = 0, \\ 1, & \text{if } n = 1, \\ xF_{n-1}(x) + F_{n-2}(x), & \text{if } n \geq 2, \end{cases} \quad (5)$$

that the Fibonacci polynomials are generated by a matrix  $Q_2$ ,

$$Q_2 = \begin{pmatrix} x & 1 \\ 1 & 0 \end{pmatrix}, \quad Q_2^n = \begin{pmatrix} F_{n+1}(x) & F_n(x) \\ F_n(x) & F_{n-1}(x) \end{pmatrix} \quad (6)$$

TABLE 1

Fibonacci polynomials	Coefficient array				
$F_0(x) = 0$	0				
$F_1(x) = 1$	1				
$F_2(x) = x$	1				
$F_3(x) = x^2 + 1$	1	1			
$F_4(x) = x^3 + 2x$	1	2			
$F_5(x) = x^4 + 3x^2 + 1$	1	3	1		
$F_6(x) = x^5 + 4x^3 + 3x$	1	4	3		
$F_7(x) = x^6 + 5x^4 + 6x^2 + 1$	1	5	6	1	
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$

can be verified quite easily by mathematical induction. The first few Fibonacci polynomials and the array of their coefficients are shown in Table 1 [2].

A sequence is *periodic* if, after a certain point, it consists of only repetitions of a fixed subsequence. The number of elements in the repeating subsequence is called the *period of the sequence*. For example, the sequence  $a, b, c, d, e, b, c, d, e, b, c, d, e, \dots$ , is periodic after the initial element  $a$  and has period 4. A sequence is *simply periodic* with period  $k$  if the first  $k$  elements in the sequence form a repeating subsequence. For example, the sequence  $a, b, c, d, a, b, c, d, a, b, c, d, \dots$ , is simply periodic with period 4 [4]. The minimum period length of  $(F_i \bmod n)_{i=-\infty}^{\infty}$  sequence is stated by  $k(n)$  and is named Wall number of  $n$  [5].

**Theorem 2.**  $k(n)$  is an even number for  $n \geq 3$  [5].

## 2. The Generalized Sequence of Fibonacci Polynomials Modulo $m$

Reducing the generalized sequence of coefficient and exponent of each Fibonacci polynomials term by a modulus  $m$ , we can get a repeating sequence, denoted by

$$\{F(x)^m\} = \{F_0(x)^m, F_1(x)^m, \dots, F_n(x)^m, \dots\}, \quad (7)$$

where  $F_i(x)^m = F_n(x) \pmod{m}$ . Let  $hF(x)^m$  denote the smallest period of  $\{F(x)^m\}$ , called the period of the generalized Fibonacci polynomials modulo  $m$ .

**Theorem 3.**  $\{F(x)^m\}$  is a periodic sequence.

*Proof.* Let  $S_2 = \{(x_1, x_2) : 1 \leq x_i \leq 2\}$  where  $x_i$  is reduction coefficient and exponent of each term in  $F_n(x)$  polynomials modulo  $m$ . Then, we have  $|S_2| = (m^m)^2$  being finite, that is, for any  $i > j$ , there exist natural numbers  $i$  and  $j$

$$\begin{aligned} F_{i+1}(x)^m &= F_{j+1}(x)^m, \\ F_{i+2}(x)^m &= F_{j+2}(x)^m, \dots, F_{i+k}(x)^m = F_{j+k}(x)^m. \end{aligned} \quad (8)$$

By definition of the generalized Fibonacci polynomials we have that  $F_i(x)^m = xF_{i-1}(x)^m + F_{i-2}(x)^m$  and  $F_j(x)^m = xF_{j-1}(x)^m + F_{j-2}(x)^m$ . Hence,  $F_i(x)^m = F_j(x)^m$ , and then it follows that

$$\begin{aligned} F_{i-1}(x)^m &= F_{j-1}(x)^m, \\ F_{i-2}(x)^m &= F_{j-2}(x)^m, \dots, F_{i-j}(x)^m = F_{j-j}(x)^m = F_0(x)^m \end{aligned} \quad (9)$$

which implies that the  $\{F(x)^m\}$  is a periodic sequence.  $\square$

*Example 4.* For  $m = 2$ ,  $\{F(x)^2\}$  sequence is  $F_0(x)^2 = 0$ ,  $F_1(x)^2 = 1$ ,  $F_2(x)^2 = x$ ,  $F_3(x)^2 = x^2 + 1 = x^0 + 1 = 2 = 0$ ,  $F_4(x)^2 = 0x + x = x$ ,  $F_5(x)^2 = x^2 + 0 = x^0 + 0 = 1$ ,  $F_6(x)^2 = x + x = 2x = 0$ ,  $F_7(x)^2 = 0x + 1 = 1$ . We have  $\{F(x)^2\} = \{0, 1, x, 0, x, 1, 0, 1, \dots\}$ , and then repeat. So, we get  $hF(x)^2 = 6$ .

Given a matrix  $A = (h_{ij}(x))$  where  $h_{ij}(x)$ 's being polynomials with real coefficients,  $A \pmod{m}$  means that every entry of  $A$  is modulo  $m$ , that is,  $A \pmod{m} = (h_{ij}(x) \pmod{m})$ . Let  $\langle Q_2 \rangle_m = \{Q_2^i \pmod{m} \mid i \geq 0\}$  be a cyclic group and  $|\langle Q_2 \rangle_m|$  denote the order of  $\langle Q_2 \rangle_m$  where  $Q_2^i \pmod{m}$  is reduction coefficient and exponent of each polynomial in  $Q_2^i$  matrix modulo  $m$ .

**Theorem 5.** One has  $hF(x)^m = |\langle Q_2 \rangle_m|$ .

*Proof.* Proof is completed if it is that  $hF(x)^m$  is divisible by  $|\langle Q_2 \rangle_m|$  and that  $|\langle Q_2 \rangle_m|$  is divisible by  $hF(x)^m$ . Fibonacci polynomials are generated by a matrix  $Q_2$ ,

$$Q_2 = \begin{pmatrix} x & 1 \\ 1 & 0 \end{pmatrix}, \quad Q_2^n = \begin{pmatrix} F_{n+1}(x) & F_n(x) \\ F_n(x) & F_{n-1}(x) \end{pmatrix}. \quad (10)$$

Thus, it is clear that  $|\langle Q_2 \rangle_m|$  is divisible by  $hF(x)^m$ . Then we need only to prove that  $hF(x)^m$  is divisible by  $|\langle Q_2 \rangle_m|$ . Let  $hF(x)^m = t$ . It is seen that  $Q_2^t = \begin{pmatrix} F_{t+1}(x) & F_t(x) \\ F_t(x) & F_{t-1}(x) \end{pmatrix}$ . Hence  $Q_2^t = I \pmod{m}$ . We get that  $|\langle Q_2 \rangle_m|$  is divisible by  $t$ . That is,  $hF(x)^m$  is divisible by  $|\langle Q_2 \rangle_m|$ . So, we get  $hF(x)^m = |\langle Q_2 \rangle_m|$ .  $\square$

**Theorem 6.**  $hF(x)^p = pk(p)$  where  $p$  is a prime number.

*Proof.* It is completed if it is that  $hF(x)^p$  is divisible by  $pk(p)$  and that  $pk(p)$  divisible by  $hF(x)^p$ . From Theorem 5  $Q_2^{pk(p)} = \begin{pmatrix} F_{pk(p)+1}(x) & F_{pk(p)}(x) \\ F_{pk(p)}(x) & F_{pk(p)-1}(x) \end{pmatrix}$ ,  $Q_2^{hF(x)^p} = I \pmod{p}$  for  $Q_2 = \begin{pmatrix} x & 1 \\ 1 & 0 \end{pmatrix}$ . Also,  $Q_2^{pk(p)} = \begin{pmatrix} F_{pk(p)+1}(x) & F_{pk(p)}(x) \\ F_{pk(p)}(x) & F_{pk(p)-1}(x) \end{pmatrix}$ . So, we get  $Q_2^{pk(p)} = I \pmod{p}$ . Thus  $pk(p)$  is divisible by  $hF(x)^p$ . Moreover  $pk(p)$  is divisible by  $hF(x)^p$ . Since  $|\langle Q_2 \rangle_p| = hF(x)^p$ ,  $hF(x)^p$  is divisible by  $pk(p)$ . Therefore  $hF(x)^p = pk(p)$ .  $\square$

**Theorem 7.**  $hF(x)^p$  is an even number where  $p$  is a prime number.

*Proof.* It has been shown that  $hF(x)^p = pk(p)$  in Theorem 6. If it is stated that  $pk(p)$  is an even number then proof is

TABLE 2: Periods of the sequence of Fibonacci polynomials modulo  $p$ .

$p$	$k(p)$	$hF(x)^p$	Result
2	3	6	$hF(x)^2 = 2k(2)$
7	16	112	$hF(x)^7 = 7k(7)$
37	76	2812	$hF(x)^{37} = 37k(37)$
103	208	21424	$hF(x)^{103} = 103k(103)$
181	90	16290	$hF(x)^{181} = 181k(181)$
241	240	57840	$hF(x)^{241} = 241k(241)$
373	748	279004	$hF(x)^{373} = 373k(373)$
653	1308	854124	$hF(x)^{653} = 653k(653)$
853	1708	1456924	$hF(x)^{853} = 853k(853)$

completed. By Theorem 2,  $k(p)$  is an even number and  $p$  is an even number for  $p \geq 3$ . Hence  $pk(p)$  is always an even number. That is,  $hF(x)^p$  is an even number.

Table 2 shows some periods of sequence of coefficient and exponent of Fibonacci polynomials modulo, which is a prime number, by using  $k(p)$ .  $\square$
