

Genus theory and governing fields

Christian Maire

ABSTRACT. In this note we develop an approach to genus theory for a Galois extension L/K of number fields by introducing some governing field. When the restriction of each inertia group to the (local) abelianization is annihilated by a fixed prime number p , this point of view allows us to estimate the genus number of L/K with the aid of a subspace of the governing extension generated by some Frobenius elements. Then given a number field K and a possible genus number g , we derive information about the smallest prime ideals of K for which there exists a degree p cyclic extension L/K ramified only at these primes and having g as genus number.

1. Introduction

1.1. Let us start to recall a vague principle of genus theory in abelian extensions L/K of number fields: “the more L/K is ramified, the larger the class group of L must be”. The reason is the following one: as we shall see, the genus field of L/K is related to the ray class field $K_{\mathfrak{m}}$ of K for a certain modulus \mathfrak{m} built over the set of ramification of L/K ; usually the ramification of $LK_{\mathfrak{m}}/K$ is absorbed in L/K , thus by class field theory the class group $\text{Cl}(L)$ of L maps onto $\text{Gal}(LK_{\mathfrak{m}}/L)$, and this last one “grows with \mathfrak{m} ”.

Let us introduce the objects more precisely. Let L/K be a Galois extension of number fields. Denote by K^H (resp. L^H) the Hilbert class field of K

(resp. of L), and consider $M_{L/K}/K$ the maximal abelian extension of K inside L^H/K . The compositum $K^* := LM_{L/K}$ is called the *genus field* of the extension L/K , and the quantity $g^* = g(L/K)^* = [K^* : L]$ its *genus number*. Let $L^{ab} = M_{L/K} \cap L$ be the maximal abelian subextension of L/K . Then the relation

$$g^* = \frac{|\text{Cl}(K)|}{[L^{ab} : K]} \cdot [M_{L/K} : K^H]$$

shows that, when the class group of K is known, it is easy to pass from $g := g(L/K) = [M_{L/K} : K^H]$ to g^* .

Since the 1950's, genus theory has been studied and developed by many authors. But let us simply mention the initial works of Hasse [9], Leopoldt [13], Fröhlich [3], Furuta [4], Razar [17], etc. For a more recent development, see [5, Chapter IV, §4] for example.

The aim of this note is to develop a new point of view of genus theory in L/K by introducing some governing extension F/K thanks to Kummer duality. We then obtain that $g(L/K)$ is related to the kernel of a morphism Θ_S involving some Frobenius elements in $\text{Gal}(F/K)$. The quantity $g(L/K)$ is more directly connected to Θ_S , so in what follows we consider g instead of g^* .

Our work has been inspired by the book of Gras [5, Chapter V], by [7], by [8], and by [16, §5].

1.2. To simplify the presentation of our first result, take a prime number $p > 2$ and let L/K be a tamely ramified abelian extension where all the inertia groups are annihilated by p . Denote by $S = \{\mathfrak{p}_1, \dots, \mathfrak{p}_s\}$ the set of ramification of L/K . Put $K' = K(\mu_p)$ and $F = K'(\sqrt[p]{\mathcal{O}_K^\times})$, where \mathcal{O}_K^\times is the group of units of the ring of integers \mathcal{O}_K of K : the number field F is *the governing field* of our study. For each prime ideal $\mathfrak{p} \in S$, choose a prime ideal \mathfrak{P} in $\mathcal{O}_{K'}$ above \mathfrak{p} and put $\sigma_{\mathfrak{p}} := \sigma_{\mathfrak{P}}$, the Frobenius element at \mathfrak{P} in $\text{Gal}(F/K')$. Consider the morphism Θ_S defined as follows:

$$\begin{aligned} \Theta_S : (\mathbb{F}_p)^s &\longrightarrow \text{Gal}(F/K') \\ (a_1, \dots, a_s) &\mapsto \prod_{i=1}^s \sigma_{\mathfrak{p}_i}^{a_i} . \end{aligned}$$

Typically, our point of view allows us to obtain the following:

Theorem 1.1. *Under the above assumptions, one has $g(L/K) = \#\ker(\Theta_S)$.*

In Section 3.4 we give a more general version of Theorem 1.1, but the one here shows clearly the flavor of our work: some relationship between the genus number of L/K and some Frobenius elements in a governing extension.

Before we present the next result, let us introduce more notation. If K is a number field, let $(r_{K,1}, r_{K,2})$ be its signature and put $r_K = r_{K,1} + r_{K,2} - 1 + \delta_{K,p}$, where $\delta_{K,p} = 1$ or 0 according $\mu_p \subset K$ or not, where μ_p is the group of p th roots of unity.

Definition 1.2. Let p be a prime number and let S be a finite set of places of K . A degree p cyclic extension L/K is called S -totally ramified if S is exactly the set of ramification of L/K .

One also obtains:

Theorem 1.3. Let K be a number field. Let $s \geq 1$ and $k \geq 1$ be two integers such that $s - r_K \leq k \leq s$, and let p be a prime number. Then there exist infinitely many sets S of places of K with $|S| = s$, such that there exists a degree p cyclic extension L/K , S -totally ramified, with $g(L/K) = p^k$. Moreover, assuming GRH,

- (i) when p is fixed, a such set S can be chosen such that the absolute norm of each $\mathfrak{p} \in S$ is $O(s \log s)$.
- (ii) when s is fixed, a such set S can be chosen such that the absolute norm of each $\mathfrak{p} \in S$ is $O(p^{2r_K+2}(\log p)^2)$.

1.3. This note contains four sections. In §2 we recall well-know results in genus theory. In §3 we present and develop the main idea of this note: to connect the genus number of a Galois extension L/K , where the restriction of each inertia group to the abelianization of the local extension is annihilated by a fixed prime number p , to the kernel of some morphism Θ_S involving some Frobenius elements; when the extension L/K is abelian and the ramification is tame, we recover Theorem 1.1. In the last section we prove Theorem 1.3.

We introduce some additional notation before proceeding to the next section. Let p be a prime number. For every finitely generated \mathbb{Z} -module A , we denote by $d_p A := \dim_{\mathbb{F}_p} \mathbb{F}_p \otimes A$, the p -rank of A .

We fix an algebraic closure $\overline{\mathbb{Q}}$ of \mathbb{Q} . If K is a number field and $v|\ell$ (possibly $\ell = \infty$) a place of K , we denote by K_v the completion of K at v . We then also fix an embedding ι_v of \mathbb{Q} in $\overline{\mathbb{Q}}_\ell$ such that $\iota_v(K)\mathbb{Q}_\ell = K_v$; if L/K is an extension of number fields we put $L_v := \iota_v(L)\mathbb{Q}_\ell$.

If K_v is a local field, we denote by v_{K_v} the normalized valuation of K_v , and by $\mathcal{U}_{K_v} = \{x \in L_v, v_{K_v}(x) > 0\}$ the groups of units of K_v . When there is no possible confusion, we write v for the valuation and \mathcal{U}_v for the units.

If $K_v = \mathbb{R}$ or \mathbb{C} , we put $\mathcal{U}_v = K_v^\times$.

Acknowledgments. The author thanks Georges Gras for encouragement and constructive observations, Philippe Lebacque for stimulating exchanges, and the anonymous referee for the careful reading of the paper.

2. Genus theory: basic results

2.1. Genus field and ray class field. Let L/K be a Galois extension of number fields of set of ramification T . For a place v of K , denote by $D_v := \text{Gal}(L_v/K_v)$ the local Galois group at v , and consider $D_v^{ab} = \text{Gal}(L_v^{ab}/K_v)$ the abelianization of D_v , where here L_v^{ab}/K_v is the maximal abelian subextension of L_v/K_v . Let $I_v := I(L_v/K_v) \subset D_v$ be the inertia subgroup, and $I_v^{ab} :=$

$I(L_v^{ab}/K_v)$ be the restriction of I_v to L_v^{ab} . If v is an archimedean place, one always has $I_v = D_v \simeq D_v^{ab}$.

Let $W_v \subset \mathcal{U}_v := \mathcal{U}_{K_v}$ be the kernel of the Artin map $\text{Art}_{L_v/K_v} : \mathcal{U}_v \rightarrow I_v^{ab}$. Of course, $W_v = N_{L_v/K_v} \mathcal{U}_{L_v}$, where N_{L_v/K_v} is the norm map of L_v/K_v . Clearly, $W_v = \mathcal{U}_v$ when v is unramified in L/K .

Denote by K_m the ray class field of K corresponding by the global Artin map to the group of idèles $W := \prod_v W_v$.

Let $S := \{v \in T, I_v^{ab} \neq \{1\}\}$ be the set of places v of K for which I_v^{ab} is not trivial. Put $\mathcal{U}_S := \prod_{v \in S} \mathcal{U}_v$ and $W_S = \prod_{v \in S} W_v$. The following proposition may be found in [4, Proposition 1]:

Proposition 2.1. *One has $M_{L/K} = K_m$. Moreover,*

$$\text{Gal}(K_m/K^H) \simeq \mathcal{U}_S / \iota_S(\mathcal{O}_K^\times) W_S,$$

where ι_S is the natural embedding.

Proof. One has $M_{L/K} \subset K_m$. Indeed, take a place v of K and $\varepsilon \in W_v$. Then ε is a norm in L_v/K_v of some unit ε_0 in L_v . As $M_{L/K}L/L$ is unramified at v , the unit ε_0 is a norm in the local extension $(M_{L/K})_v L_v/L_v$, and then ε is a norm in $(M_{L/K})_v L_v/K_v$, which implies that $\text{Art}_{(M_{L/K})_v/K_v}(\varepsilon)$ is trivial. Then the global Artin map of the extension $M_{L/K}/K$ vanishes on W , and thus $M_{L/K} \subset K_m$ by maximality of K_m .

Moreover $K_m L/L$ is an unramified abelian extension. Indeed, for every place v of K , the local Artin symbol indicates that $\mathcal{U}_v/W_v \rightarrow I((K_m)_v/K_v)$ and that $I_v^{ab} = I(L_v/K_v)^{ab} \simeq \mathcal{U}_v/W_v$. By the property of the Artin symbol, one then has $I(L_v^{ab}(K_m)_v/K_v) \simeq \mathcal{U}_v/W_v$, thus $I(L_v^{ab}(K_m)_v/L_v^{ab}) = \{1\}$ and $(K_m)_v L_v/L_v$ is unramified. By maximality of $M_{L/K}$ one deduces that $K_m \subset M_{L/K}$, and finally that $M_{L/K} = K_m$.

By class field theory one has

$$\text{Gal}(K_m/K^H) \simeq \prod_v \mathcal{U}_v / \iota(\mathcal{O}_K^\times) W \simeq \mathcal{U}_T / \iota_T(\mathcal{O}_K^\times) W_T,$$

where $\iota : \mathcal{O}_K^\times \rightarrow \prod_v \mathcal{U}_v$ is the natural embedding. To conclude, observe that for $v \in T \setminus S$, $\mathcal{U}_v = W_v$, and then $\mathcal{U}_T/W_T \simeq \mathcal{U}_S/W_S$. □

2.2. Formula and exact sequence in genus theory. If L/K is a Galois extension, denote by $\mathcal{O}_K^\times \cap N_{L/K}$ the units \mathcal{O}_K^\times of \mathcal{O}_K that are local norms in L/K .

Theorem 2.2. *Let L/K be a Galois extension of number fields of set of ramification T . One has*

(i) *the genus formula:*

$$g(L/K) = \frac{\prod_{v \in T} \#I_v^{ab}}{(\mathcal{O}_K^\times : \mathcal{O}_K^\times \cap N_{L/K})},$$

(ii) *the genus exact sequence:*

$$1 \longrightarrow \mathcal{O}_K^\times / \mathcal{O}_K^\times \cap N_{L/K} \longrightarrow \prod_{v \in T} I_v^{ab} \longrightarrow \text{Gal}(M_{L/K}/K^H) \longrightarrow 1.$$

For the proof of Theorem 2.2, see for example [5, Chapter IV, §4]. See also [14].

Corollary 2.3. *Let L/K be a Galois extension where all the I_v^{ab} are annihilated by a fixed prime number p . Then $\text{Gal}(M_{L/K}/K^H)$ is of exponent p .*

Remark 2.4. *Let us recall at least two applications of the genus exact sequence:*

- (i) *the construction of number fields having an infinite Hilbert p -class field tower (see for example [18]);*
- (ii) *the study of Greenberg’s conjecture for totally real number fields (see for example the recent work of Gras [6]).*

Remark 2.5. *For genus theory in more general contexts see for example [5, Chapter IV, §4], [11, Chapter III, §2] or [14].*

3. Kummer theory and governing field

Let L/K be a Galois extension of set of ramification T . We keep the notations of §2 (see also the last few paragraphs of Section 1).

From now on, we assume that all the inertia groups I_v^{ab} are annihilated by a fixed prime number p .

Put $S := \{v \in T, I_v^{ab} \neq \{1\}\}$ and let us write $S = S_0^{ta} \cup S_0^{wi} \cup S_\infty$, where S_0^{ta} is the set of finite places of S coprime to p (called tame places), S_0^{wi} is the set of places S dividing p (called wild places), and S_∞ contains the ramified archimedean places. In particular $S_\infty = \emptyset$ when $[L : K]$ is odd. Observe that by hypothesis, for $v \in S_0^{ta}$, the local field K_v contains the p -roots of the unity. Put

$$s = \#S_\infty + \#S_0^{ta} + \sum_{v \in S_0^{wi}} d_p I_v^{ab}.$$

Remark 3.1. *Following Section 2.1, for each place v of K one has $U_v^p \subset W_v$; for $v \in S_0^{ta} \cup S_\infty$ one even has $W_v = U_v^p$.*

3.1. Governing field. Fix now $\zeta \in \overline{\mathbb{Q}}$, a primitive p th root of the unity, and put $\mu_p = \langle \zeta \rangle$.

Let us consider the number fields $K' = K(\zeta)$ and $F = K'(\sqrt[p]{\mathcal{O}_K^\times})$: the field F is the *governing field* of our study. First, we give an upper bound for the absolute value of the discriminant d_F of F .

Proposition 3.2. *One has*

$$|d_F| \leq |d_K|^{(p-1)p^{r_K}} \cdot p^{[K:\mathbb{Q}](p-1)(4p^{r_K}-3)}.$$

Proof. Observe that F/K is unramified outside p . For a better readability of the proof, we change a little bit the principle of notations for local extensions followed since the beginning. Let $v|p$ be a wild place of K , and let $w|v$ be a place of K' above v . Denote by w the normalized valuation of K'_w , and by e_w (respectively f_w) the absolute ramification index (resp. inertia degree) of w .

Let us start to recall that the w -valuation of the conductor of a local degree p cyclic extension L_w/K'_w is less than $1 + 2e_w$ (indeed, every unit $\varepsilon \in K'_w$ such that $w(\varepsilon - 1) \geq 1 + 2e_w$ is a p th power). By the conductor-discriminant formula (see for example [15, Chapter VII, §12, Theorem 11.9]) we get

$$w(\text{disc}(F_w/K'_w)) \leq (1 + 2e_w)(p^{r_K} - 1).$$

Hence by the discriminants formula in a tower of number fields (see for example [15, hapter III, §2, Corollary 2.10]), we finally obtain

$$(1) \quad |d_F| \leq |d_{K'}|^{[F:K']} \cdot p^{\sum_{w|p} (1+2e_w)f_w(p^{r_K}-1)} \leq |d_{K'}|^{p^{r_K}} \cdot p^{3(p-1)(p^{r_K}-1)[K:\mathbb{Q}]},$$

where here the sum is taken over the places w of K' above p .

The extension K'/K is tamely ramified (the v -valuation of the conductor is ≤ 1) and then

$$(2) \quad |d_{K'}| = |d_K|^{[K':K]} \cdot p^{\sum_{v|p} f_v \sum_{w|v} f(w/v)(e(w/v)-1)} \leq \left(|d_K| \cdot p^{[K:\mathbb{Q}]} \right)^{p-1},$$

where the sum is taken over the wild places v of K , and $e(w|v) = e_w/e_v$ (resp. $f(w|v) = f_w/f_v$) is the ramification index (resp. inertia degree) of w in K'/K .

Inequalities (1) and (2) then allow us to conclude. □

If M is a \mathbb{F}_p -module, put $M^\vee := \text{hom}(M, \mu_p)$. Let

$$\psi : (\mathcal{O}_K^\times / (\mathcal{O}_K^\times)^p)^\vee \rightarrow \text{Gal}(F/K')$$

be the isomorphism issue from Kummer duality. Let us recall how this isomorphism works: for $\chi \in (\mathcal{O}_K^\times / (\mathcal{O}_K^\times)^p)^\vee$ one associates the element $\sigma_\chi := \psi(\chi) \in \text{Gal}(F/K')$ defined as follows:

$$\sigma_\chi(\sqrt[p]{\varepsilon}) = \chi(\varepsilon) \cdot \sqrt[p]{\varepsilon}.$$

For more details see for example [5, Chapter I, §6, exercice 6.2.2].

3.2. Tame places and Frobenius elements. Let us take $v \in S_0^{ta}$. As before (see the last few paragraphs of Section 1), we fix an embedding $\iota_v : \overline{\mathbb{Q}} \hookrightarrow \overline{\mathbb{Q}}_p$ such that $\iota_v(K)\mathbb{Q}_p = K_v$. Observe that $K_v = K'_v$. Let us denote by $\sigma_v (= \sigma_{v_{K'}})$ the Frobenius of $v_{K'}$ in $\text{Gal}(F/K')$.

Let $N(v_{K'})$ be the order of the residue field of K'_v . Take now $\zeta_v \in \mathcal{U}_v$ such that $\zeta_v^{(N(v_{K'})-1)/p} = \iota_v(\zeta)$ and consider the generator χ_v of $(\mathcal{U}_v/\mathcal{U}_v^p)^\vee$ defined by $\chi_v(\zeta_v) = \zeta$. Thanks to ι_v , the character χ_v can be viewed as an element of $(\mathcal{O}_K^\times / (\mathcal{O}_K^\times)^p)^\vee$.

Proposition 3.3. *One has $\psi(\chi_v \circ \iota_v) = \sigma_v$.*

Proof. Put $\sigma = \psi(\chi_v \circ \iota_v)$ and take $\varepsilon \in \mathcal{O}_K^\times$. Let $a_v(\varepsilon) \in \mathbb{F}_p$ such that $\iota_v(\varepsilon)\mathcal{U}_v^p = \zeta_v^{a_v(\varepsilon)}\mathcal{U}_v^p$. Then by Kummer theory,

$$\sigma(\sqrt[p]{\varepsilon})/\sqrt[p]{\varepsilon} = \chi_v(\iota_v(\varepsilon)) = \zeta^{a_v(\varepsilon)}.$$

But by definition, the Frobenius element σ_v satisfies the property:

$$\sigma_v(\sqrt[p]{\varepsilon})/\sqrt[p]{\varepsilon} \equiv \varepsilon^{(N(v_{K'})-1)/p} \pmod{v_{K'}}.$$

Here $a \equiv b \pmod{v_{K'}}$ means that $v_{K'}(a - b) > 0$. Hence

$$\iota_v\left(\sigma_v(\sqrt[p]{\varepsilon})/\sqrt[p]{\varepsilon}\right) \equiv \iota_v(\zeta^{a_v(\varepsilon)}) \pmod{v_{K'}},$$

which shows that $\sigma(\sqrt[p]{\varepsilon}) = \sigma_v(\sqrt[p]{\varepsilon})$. □

Remark 3.4. If we choose another embedding $\iota_{v'} : \overline{\mathbb{Q}} \hookrightarrow \overline{\mathbb{Q}_\ell}$ (instead of ι_v), then by Kummer duality and by the property of the Artin symbol, one has $\sigma_{v'} = \sigma_v^a$ for some $a \in \mathbb{F}_p^\times$.

3.3. The other places.

3.3.1. Wild places. Here now take $v|p$. Recall that $I_v \simeq (\mathbb{Z}/p\mathbb{Z})^{a_v}$. By the Artin map and by Kummer duality, one has

$$I_v^\vee \simeq (\mathcal{U}_v/W_v)^\vee \hookrightarrow (\mathcal{U}_v/\mathcal{U}_v^p)^\vee.$$

Then take an \mathbb{F}_p -basis $\{\chi_v^{(i)}, i = 1, \dots, a_v\}$ of $(\mathcal{U}_v/W_v)^\vee$. For $i = 1, \dots, a_v$, consider $\sigma_v^{(i)} \in \text{Gal}(F/K')$ defined as follows: for $\varepsilon \in \mathcal{O}_K^\times$ put

$$\sigma_v^{(i)}(\sqrt[p]{\varepsilon}) = \chi_v^{(i)}(\iota_v(\varepsilon)) \cdot \sqrt[p]{\varepsilon}.$$

3.3.2. Infinite places. Take $p = 2$ and let v be a real place of K . Here $\mathcal{U}_v/\mathcal{U}_v^2 \simeq \mathbb{R}^\times/\mathbb{R}^{\times,+}$. Then for $\varepsilon \in \mathcal{O}_K^\times$ put

$$\sigma_v(\sqrt{\varepsilon}) = \text{sign}(\iota_v(\varepsilon))\sqrt{\varepsilon},$$

where $\text{sign}(\iota_v(\varepsilon))$ is the sign of the embedding $\iota_v(\varepsilon)$ of ε in K_v . Of course $\sigma_v = \sigma_{\chi_v}$, where χ_v is the non trivial character of $\mathcal{U}_v/\mathcal{U}_v^2$.

3.4. Key map and main result. Let Θ_S be the linear map

$$\Theta_S : (\mathcal{U}_S/W_S)^\vee \rightarrow \text{Gal}(F/K')$$

defined as follows:

- (i) for $v \in S_0^{ta} \cup S_\infty$, put $\Theta_S(\chi_v) = \sigma_v$,
- (ii) for $v \in S_0^{wi}$, put $\Theta_S(\chi_v^{(i)}) = \sigma_v^{(i)}$.

While fixing an isomorphism $\text{Gal}(F/K') \simeq \mathbb{F}_p^{r_K}$ we see that Θ_S is a linear map from \mathbb{F}_p^s to $\mathbb{F}_p^{r_K}$.

Theorem 3.5. Under the assumptions of section 3, the Artin map induces the isomorphism $\ker(\Theta_S) \simeq \text{Gal}(K_m/K^H)^\vee$.

Proof. Let us start with the exact sequence (see Proposition 2.1)

$$1 \longrightarrow \iota_S(\mathcal{O}_K^\times/(\mathcal{O}_K^\times)^p) \longrightarrow \mathcal{U}_S/\mathcal{W}_S \longrightarrow \text{Gal}(\mathbb{K}_m/\mathbb{K}^H) \longrightarrow 1$$

and take its Kummer dual to obtain

$$\begin{array}{ccccccc}
 1 & \longrightarrow & \text{Gal}(\mathbb{K}_m/\mathbb{K}^H)^\vee & \longrightarrow & (\mathcal{U}_S/\mathcal{W}_S)^\vee & \longrightarrow & (\iota_S(\mathcal{O}_K^\times/(\mathcal{O}_K^\times)^p)^\vee \longrightarrow 1 \\
 & & & & \downarrow \text{dotted} & & \downarrow \\
 & & \text{Gal}(\mathbb{F}/\mathbb{K}') & \xleftarrow[\psi]{\cong} & (\mathcal{O}_K^\times/(\mathcal{O}_K^\times)^p)^\vee & &
 \end{array}$$

Observe that

$$(\mathcal{U}_S/\mathcal{W}_S)^\vee \simeq \prod_{v \in S_0^{ta} \cup S_\infty} (\mathcal{U}_v/\mathcal{U}_v^p)^\vee \prod_{v \in S_0^{wi}} (\mathcal{U}_v/\mathcal{W}_v)^\vee.$$

Thus, by Proposition 3.3 and sections 3.3.1 and 3.3.2, the induced map from $(\mathcal{U}_S/\mathcal{W}_S)^\vee$ to $\text{Gal}(\mathbb{F}/\mathbb{K}')$ is exactly Θ_S . Hence we get:

$$\text{Gal}(\mathbb{K}_m/\mathbb{K}^H)^\vee \simeq \ker \left((\mathcal{U}_S/\mathcal{W}_S)^\vee \xrightarrow{\Theta_S} \text{Gal}(\mathbb{F}/\mathbb{K}') \right).$$

The proof is complete. □

Corollary 3.6. *One has $g(\mathbb{L}/\mathbb{K}) = \# \ker(\Theta_S)$. In particular,*

$$s - r_K \leq d_p \text{Gal}(\mathbb{M}_{\mathbb{L}/\mathbb{K}}/\mathbb{K}^H) \leq s.$$

Proof. This is a consequence of Theorem 3.5 and Proposition 2.1. □

Observe that Theorem 1.1 is a consequence of Corollary 3.6.

3.5. Examples.

3.5.1. Imaginary quadratic fields. Take $p = 2$ and let \mathbb{L}/\mathbb{Q} be an imaginary quadratic extension of discriminant d . The field $\mathbb{F} = \mathbb{Q}(\sqrt{-1})$ is the governing field and, thanks to $S_\infty = \{v_\infty\}$, the map Θ_S is onto. Then $g(\mathbb{L}/\mathbb{Q}) = 2^s$ and $g^* = 2^{s-1}$, where s is the number of primes dividing d .

3.5.2. Real quadratic fields. Take $p = 2$ and let \mathbb{L}/\mathbb{Q} be a real quadratic extension of discriminant d . Here $S_\infty = \emptyset$ and $\mathbb{F} = \mathbb{Q}(\sqrt{-1})$ is the governing field. Then Θ_S is the zero map if and only if every odd prime ℓ dividing d is congruent to $1 \pmod{4}$; in this case $g = 2^s$. Otherwise Θ_S is onto and $g = 2^{s-1}$, where s is the number of primes dividing d .

3.5.3. Cubic fields. As studied in [1] and [2], the situation where $p = 3$, $\mathbb{K} = \mathbb{Q}(\mu_3)$ and $\mathbb{L} = \mathbb{K}(\sqrt[3]{d})$, $d \in \mathbb{Z}_{\geq 1}$, is also interesting to describe. Indeed in this case the governing extension is the extension $\mathbb{Q}(\mu_9)/\mathbb{Q}(\mu_3)$. Here $s - 2 \leq d_3 \text{Gal}(\mathbb{K}^*/\mathbb{L}) \leq s - 1$, and to have the exact value of $d_3 \text{Gal}(\mathbb{K}^*/\mathbb{L})$, one needs to determine: (i) the number s of prime ideals \mathfrak{p} in \mathcal{O}_K ramified in \mathbb{L}/\mathbb{K} , and (ii) if the map Θ_S is trivial or not (here $d_3 \text{Im}(\Theta_S) \leq 1$). And these two conditions are characterized by the congruences in $\mathbb{Z}/9\mathbb{Z}$ of the

prime numbers ℓ that divide d . Typically, if there exists a prime number $\ell|d$, $\ell \neq 3$, such that 3 divides the order of ℓ in $(\mathbb{Z}/9\mathbb{Z})^\times$, then $\text{Im}(\Theta_S) \simeq \mathbb{F}_3$.

4. Proof of Theorem 1.3

Let $s, k \in \mathbb{Z}_{>0}$ such that $s - r_K \leq k \leq s$. Put $n = s - k$.

First, one has to enlarge the governing field $F = K'(\sqrt[p]{\mathcal{O}_K^\times})$ by considering the number field

$$\tilde{F} := F(\sqrt[p]{a_1}, \dots, \sqrt[p]{a_h}),$$

where the a_i 's are such that $a_i \mathcal{O}_K = \mathfrak{a}_i^p \in \text{Cl}(K)$ and the family $\{\mathfrak{a}_1, \dots, \mathfrak{a}_h\}$ forms an \mathbb{F}_p -basis of $\text{Cl}(K)[p]$ (the classes annihilated by p). One has $[\tilde{F} : K'] = p^{r_K+h}$. Let us fix an \mathbb{F}_p -basis $(e_i)_{i=1, \dots, r_K}$ of

$$\text{Gal}(\tilde{F}/K'(\sqrt[p]{a_1}, \dots, \sqrt[p]{a_h})) \simeq (\mathbb{F}_p)^{r_K}$$

and complete this basis to an \mathbb{F}_p -basis $(e_i)_{i=1, \dots, r_K+h}$ of $\text{Gal}(\tilde{F}/K') \simeq (\mathbb{F}_p)^{r_K+h}$. By the Chebotarev density theorem, let $S = \{v_1, \dots, v_s\}$ be a set of s different tame places of K such that the Frobenius elements $\sigma_{v_i} \in \text{Gal}(\tilde{F}/K') \subset \text{Gal}(\tilde{F}/K)$ of v_i satisfy:

- (a) $\sigma_{v_1} = -(e_1 + \dots + e_n)$;
- (b) for $i = 2, \dots, n+1$, $\sigma_{v_i} = e_{i-1}$;
- (c) for $i = n+2, \dots, s$, $\sigma_{v_i} = 0$,

when $n \geq 1$. When $n = 0$, choose the v_i 's such that $\sigma_{v_i} = 0$, $i = 1, \dots, s$.

Observe that $\sum_{i=1}^s \sigma_{v_i} = 0$. Then by a result of Gras-Munnier [7, Theorem 1.1] (see also [5, Chapter V, §2, Corollary 2.4.2]), there exists a degree p cyclic extension L/K , S -totally ramified. Moreover, by the choice of the e_i 's and the v_i 's the morphism Θ_S , with value in $\text{Gal}(F/K')$, is of rank n . Then $\text{Gal}(M_{L/K}/K) \simeq (\mathbb{F}_p)^{s-n} = (\mathbb{F}_p)^k$ by Corollary 3.6, which proves (i) of Theorem 1.3.

Before we prove (ii) of Theorem 1.3, let us make the following observation:

Lemma 4.1. *One has $\log |d_{\tilde{F}}| \leq 2|\text{Cl}(K)| \log |d_F|$.*

Proof. Adapt Proposition 3.2. □

Remark 4.2. *Obviously one has $\tilde{F} = F$ for $p \gg 0$.*

The second point (ii) is a consequence of an effective version of the Chebotarev density theorem under GRH (see for example [12, Theorem 1.1] or [19, §2.5, Theorem 4]). Observe first that when $n > 1$ or when $p > 2$, all the Frobenius elements of (a) and (b) are in different conjugacy classes. (When $n = 1$ and $p = 2$, the Frobenius of v_1 and of v_2 are in the same conjugacy class, see the next to solve the problem). We can be certain that there exist such primes (associated to places v_i) with norm of order $O((\log |d_{\tilde{F}}|)^2) = O((\log |d_F|)^2)$.

For the places v_{n+2}, \dots, v_s , we need the following two lemmas.

Lemma 4.3. *Given $m \in \mathbb{Z}_{\geq 1}$, there exist m prime ideals $\mathfrak{p}_1, \dots, \mathfrak{p}_m$ in \mathcal{O}_K that split totally in \tilde{F}/K , all having absolute norm less than $C_{K,p}m(\log m)$, where $C_{K,p}$ is some constant depending on K and on p .*

Proof. For $x \geq 2$ let

$$\pi(x) = \left| \left\{ \text{prime ideals } \mathfrak{p} \subset \mathcal{O}_K, |\mathcal{O}_K/\mathfrak{p}| \leq x, \mathfrak{p} \text{ splits totally in } \tilde{F}/K \right\} \right|.$$

Then the effective Chebotarev density theorem under GRH indicates that $\pi(x) \geq A(x)$, where

$$A(x) = \frac{1}{[\tilde{F} : K]} \left(\frac{x}{\log(x)} - Cx^{1/2}(\log |d_{\tilde{F}}| + [\tilde{F} : \mathbb{Q}] \log x) \right),$$

C being some absolute constant. Then, by Lemma 4.1 and Proposition 3.2, taking

$$x_0 = C_{K,p}m(\log m),$$

for some constant $C_{K,p}$ depending on K and on p we are certain that $A(x_0) \geq m$ and we are done. □

Lemma 4.4. *Given $m \in \mathbb{Z}_{\geq 1}$, there exist m prime ideals $\mathfrak{p}_1, \dots, \mathfrak{p}_m$ in \mathcal{O}_K that split totally in \tilde{F}/K , all having absolute norm less than*

$$C_{K,m}p^{2r_K+2}(\log p)^2,$$

where $C_{K,m}$ is some constant depending on K and on m .

Proof. Observe that \tilde{F}/K is unramified outside p . Let ℓ be a prime number coprime to the set of ramification of \tilde{F}/\mathbb{Q} and such that $\ell \geq m$. By Bertrand’s postulate, this ℓ can be taken less than $C_K \cdot m$, where C_K is some constant depending on K . Put $N = \mathbb{Q}(\mu_\ell)$ and $N_0 = N\tilde{F}$. The extension N_0/\tilde{F} is of degree $\ell - 1$, and $|d_{N_0}| \leq |d_{\tilde{F}}|^{\ell-1}|d_N|^{[\tilde{F}:\mathbb{Q}]}$. Let us choose now m prime ideals $\mathfrak{p}_1, \dots, \mathfrak{p}_m$ in \mathcal{O}_K , all unramified in N_0/K , such that their Frobenius in $\text{Gal}(N_0/\tilde{F}) \subset \text{Gal}(N_0/K)$ are in some different conjugacy classes: by the Chebotarev density theorem (under GRH), the \mathfrak{p}_i ’s can be chosen of norm smaller than $C(\log |d_{N_0}|)^2$, where C is some absolute constant. Hence by Lemma 4.1, for $i = 1, \dots, m$, we obtain that the $N(\mathfrak{p}_i)$ ’s are smaller than

$$C \left(\ell p^{r_K+1} |\text{Cl}(K)| [K : \mathbb{Q}] \log(p^4 \ell |d_K|^{2/[K:\mathbb{Q}]}) \right)^2 \leq C_{K,m} p^{2r_K+2} (\log p)^2.$$

Finally to conclude, observe that each \mathfrak{p}_i splits totally in F/K . □
