Simplicial moves on complexes and manifolds

W B R Lickorish

Abstract Here are versions of the proofs of two classic theorems of combinatorial topology. The first is the result that piecewise linearly homeomorphic simplicial complexes are related by stellar moves. This is used in the proof, modelled on that of Pachner, of the second theorem. This states that moves from only a finite collection are needed to relate two triangulations of a piecewise linear manifold.

AMS Classification 57Q15; 52B70

Keywords Simplicial complexes, subdivisions, stellar subdivisions, stellar manifolds, Pachner moves

For Rob Kirby, a sixtieth birthday offering after thirty years of friendship

1 Introduction

A finite simplicial complex can be viewed as a combinatorial abstraction or as a structured subspace of Euclidean space. The combinatorial approach can lead to cleaner statements and proofs of theorems, yet it is the more topological interpretation that provides motivation and application. In particular, continuous functions can be approximated by piecewise linear maps, those generalisations of the simple idea represented by a saw-tooth shaped graph. To discuss piecewise linear functions it is necessary to consider simplex-preserving functions between arbitrary subdivisions of complexes (subdivisions obtained by dissecting Euclidean simplexes into smaller simplexes in a linear, but un-systematic, way). The commonly used standard treatments of piecewise linear topology and piecewise linear manifold theory, those by J F P Hudson [6], C P Rourke and B J Sanderson [13] and E C Zeeman [16], are successfully based on this idea of arbitrary subdivision. Indeed, the newly-found ability to proceed without heavy combinatorics was a key factor encouraging the renaissance of piecewise linear topology in the 1960's. However, one of the main triumphs of combinatorial topology, as developed by J W Alexander [1] and M H A Newman [9] in the 1920's and 1930's, was a result connecting the abstract and piecewise linear approaches. A proof of that result is given here. It states that

any subdivision of a finite simplicial complex can be obtained from the original complex by a finite sequence of stellar moves. These moves, explained below, change sub-collections of the simplexes in a specified manner, but there are, nonetheless, infinitely many possible such moves. A version of this result, not discussed in [6], [13] and [16], does appear in [5], but this is not easily available. Otherwise the original accounts, which use some outmoded terminology, must be consulted. The version of stellar theory given here is based on some lectures given by Zeeman in 1961.

Inaccessibility of a result hardly matters if nobody wishes to use and understand it. However in much more recent years, U Pachner [11], [12] has, *starting* with the theory of stellar moves, produced a finite set of combinatorial moves (analogous, in some way, to the well known Reidemeister moves of knot theory) that suffice to change from any triangulation of a piecewise linear manifold to any other. Much of this was foreshadowed by Newman in [9]. A discussion and proof of this, based on Pachner's work, is the task of the final section of this paper. As was pointed out by V G Turaev and O Ya Viro, such a finite set of moves can at once be used to establish the well-definedness of any manifold invariant defined in terms of simplexes. This they did, for 3-manifolds, in establishing their famous state sum invariants [15] that turned out to be the squares of the moduli of the Witten invariants. It is not so very hard to prove the combinatorial result in dimension three, though still assuming stellar theory, (see [15] or [2]). However, the result is now being used to substantiate putative topological quantum field theories in four or more dimensions. It thus seems desirable to have available, readily accessible to topologists, a complete reworking of the stellar theory and Pachner's work in a common notation as now used by topologists. Aside from their uses, these two results form a most elegant chapter in the theory of combinatorial manifolds. In addition, as explained in [8], the moves between triangulations of a manifold are a simplicial version of the moves on handle structures of a manifold that come from Cerf theory. Cerf theory, of course, has many important uses, one being in Kirby's proof of the sufficiency of the surgery moves of his calculus for 3-manifolds. A piecewise linear version of Cerf theory was not available when any of the classic piecewise linear texts was written.

2 Notation and other preliminaries

Some standard notational conventions that will be used will now be outlined, but it is hoped that basic ideas of simplicial complexes will be familiar. Simplicial complexes are objects that consist of infinitely many simplexes, which can be

thought of as elementary building blocks, glued together to make up the complex. Such a complex can be thought of as just a finite set (the vertices) with certain specified subsets (the simplexes). Pachner's results and the basic stellar subdivision theory are probably best viewed in terms of this latter abstract formulation. Although the abstraction has its virtues, to be of use in topology a simplicial complex needs to represent a topological space. Here that is taken to be a subspace of some \mathbb{R}^N . Thus in what follows a simplex will be taken to be the convex hull of its vertices, they being independent points in \mathbb{R}^N . This allows the use of certain topological words (like 'closure' and 'interior') but, more importantly, it allows the idea of an arbitrary subdivision of a complex which, in turn, permits at once the definition of the natural and ubiquitous idea of a piecewise linear map. One of the purposes of this account is to discuss the relation between the piecewise linear and abstract notions, so it may be wise to feel familiar with both interpretations of a simplicial complex. The notation $A \triangleleft B$ will mean that a simplex A is a face of simplex B ; the empty simplex \emptyset is a face of every simplex.

Definition 2.1 A (finite) simplicial complex K is a finite collection of simplexes, contained (linearly) in some \mathbb{R}^N , such that

- (1) $B \triangleleft K$ and $A \triangleleft B$ implies that $A \triangleleft K$,
- (2) $A \triangleleft K$ and $B \triangleleft K$ implies that $A \setminus B$ is a face of both A and B .

The standard complex Δ^n will be the complex consisting of all faces of an n -simplex (including the n -simplex itself); its boundary, denoted $\partial \Delta^n$, will be the subcomplex of all the proper faces of Δ^n . Sometimes the symbol A will be used ambiguously to denote a simplex A and also the simplicial complex consisting of A and all its faces.

The join of simplexes A and B will be denoted $A \ast B$, this being meaningful only when all the vertices of A and B are independent. Observe that $\emptyset \ast A = A$. The join of simplicial complexes K and L , written $K \ast L$, is $\{A \ast B : A \triangleleft K, B \triangleleft L\}$, where it is assumed that, for $A \triangleleft K$ and $B \triangleleft L$, the vertices of A and B are independent. Note that the join notation is associative and commutative.

The link of a simplex A in a simplicial complex K , denoted $\text{lk}(A; K)$, is defined by

$$\text{lk}(A; K) = \{B \triangleleft K : A \ast B \triangleleft K\}$$

The (closed) star of A in K , $\text{st}(A; K)$, is the join $A \ast \text{lk}(A; K)$.

A simplicial isomorphism between two complexes is a bijection between their vertices that induces a bijection between their simplexes. The *polyhedron* $|K|$

underlying the simplicial complex K is defined to be $[A \triangleright_K A]$ and K is called a triangulation of jKj .

A simplicial complex K^0 is a subdivision of the simplicial complex K if $jK^0j = jKj$ and each simplex of K^0 is contained linearly in some simplex of K . Two simplicial complexes K and L are piecewise linearly homeomorphic if they have subdivisions K^0 and L^0 that are simplicially isomorphic. It is straightforward to show that this is an equivalence relation. (More generally, a piecewise linear map from K to L is a simplicial map from some subdivision of K to some subdivision of L .)

Definition 2.2 A combinatorial n -ball is a simplicial complex B^n piecewise linearly homeomorphic to D^n . A combinatorial n -sphere is a simplicial complex S^n piecewise linearly homeomorphic to S^n . A combinatorial n -manifold is a simplicial complex M such that, for every vertex v of M , $\text{lk}(v; M)$ is a combinatorial $(n-1)$ -ball or a combinatorial $(n-1)$ -sphere.

It could be argued that this traditional definition is not exactly 'combinatorial'. The results described later do show it to be equivalent to other formulations with a stronger claim to this epithet. The definition of a combinatorial n -manifold is easily seen to be equivalent to one couched in terms of coordinate charts modelled on D^n with overlap maps being required to be piecewise linear [13]. By definition, a piecewise linear n -manifold is just a class of combinatorial n -manifolds equivalent under piecewise linear homeomorphism. Beware the fact that a simplicial complex K for which jKj is topologically an n -manifold is not necessarily a combinatorial n -manifold. This follows, for example, from the famous theorem of R D Edwards [4] that states that, if M is a connected orientable combinatorial 3-manifold with the same homology as the 3-sphere (there are infinitely many of these), then $jS^1 \times Mj$ is (topologically) homeomorphic to the 5-sphere. However, if jMj is not simply connected, the complex $S^1 \times M$ cannot be a combinatorial 5-manifold.

Definition 2.3 Suppose that A is an r -simplex in an abstract simplicial complex K and that $\text{lk}(A; K) = \text{lk}(A; B)$ for some $(n-r)$ -simplex $B \in K$. The bistellar move $(A; B)$ consists of changing K by removing $A \times B$ and inserting $A \times B$.

When $n = 2$, the three types of bistellar move are shown, for $\dim A = 2; 1; 0$, in Figure 1. Note that the definition is given for abstract complexes. The condition that $B \in K$ requires B to be a *new* simplex not seen in K . For complexes in \mathbb{R}^N this condition should be replaced by a requirement that $A \times B$ should exist and that $jA \times Bj \setminus jKj = jA \times Bj$.

Figure 1

Complexes related by a finite sequence of these bistellar moves and simplicial isomorphisms are called *bistellar equivalent*. The main theorem, described by Pachner [12], can now be stated as follows.

Theorem 5.9 ([9], [12]) *Closed combinatorial n -manifolds are piecewise linearly homeomorphic if and only if they are bistellar equivalent.*

There is also a version of this result for manifolds with boundary that will be discussed at the end of this paper.

3 Stellar subdivision theory

Theorem 5.9 is entirely combinatorial in nature. It can be seen as an extension of the long known ([1], [9]) combinatorial theory of stellar subdivision. This stellar theory will now be described. In outline, a definition of stellar subdivision leads at once to a definition of a stellar n -manifold, and Pachner's methods can be applied *at once* to such manifolds to prove Theorem 5.9. The classical theory, described in this section, of stellar subdivisions is needed only to show that stellar equivalence classes of stellar n -manifolds are, in fact, the same as piecewise linear homeomorphism classes of combinatorial n -manifolds.

Suppose that A is any simplex in a simplicial complex K . The operation $(A; a)$, of starring K at a point a in the interior of A , is the operation that changes K to K^0 by removing $\text{st}(A; K)$ and replacing it with $a \text{ ? } @A \text{ ? } \text{lk}(A; K)$. This is written $K^0 = (A; a)K$ or $K \stackrel{(A; a)}{\nearrow} K^0$. In the abstract setting a is just a vertex not in K . This type of operation is called a stellar *subdivision*, the inverse operation $(A; a)^{-1}$ that changes K^0 to K is called a stellar *weld*. If simplicial complexes K_1 and K_2 are related by a sequence of starring operations (subdivisions or welds) and simplicial isomorphisms, they are called stellar equivalent, written $K_1 \sim K_2$. Note that $((A; a)K) \text{ ? } L = (A; a)(K \text{ ? } L)$, so that $K_1 \sim K_2$ and $L_1 \sim L_2$ implies that $K_1 \text{ ? } L_1 \sim K_2 \text{ ? } L_2$.

There now follow the definitions of stellar balls, spheres, and manifolds. These ideas are not normally encountered as it will follow, at the end of Section 4, that they are the same as the more familiar combinatorial balls, spheres, and manifolds; in turn these are, up to piecewise linear equivalence, the even more familiar piecewise linear balls, spheres, and manifolds.

Definition 3.1 A stellar n -ball is a simplicial complex B^n stellar equivalent to B^n . A stellar n -sphere is a simplicial complex S^n stellar equivalent to S^n . A stellar n -manifold is a simplicial complex M such that, for every vertex v of M , $\text{lk}(v; M)$ is a stellar $(n-1)$ -ball or a stellar $(n-1)$ -sphere.

A first exercise with stellar ideas is to prove, for stellar balls and spheres, the following:

$$B^m \approx B^n \quad B^{m+n+1}; \quad S^m \approx S^n \quad S^{m+n+1}; \quad B^m \approx S^n \quad B^{m+n+1}.$$

Lemma 3.2 Suppose M is a stellar n -manifold.

- (1) If A is an s -simplex of M then $\text{lk}(A; M)$ is a stellar $(n-s-1)$ -ball or $(n-s-1)$ -sphere.
- (2) If $M \approx M^0$ then M^0 is a stellar n -manifold.

Proof Assume inductively that both parts of the Lemma are true for stellar r -manifolds where $r < n$. Part (ii) implies that, for $r < n$, stellar r -balls and stellar r -spheres are stellar r -manifolds.

Suppose that A is an s -simplex of M . Writing $A = v \cup B$, for v a vertex of A and B the opposite face, $\text{lk}(A; M) = \text{lk}(B; \text{lk}(v; M))$. But $\text{lk}(v; M)$ is a stellar $(n-1)$ -sphere or ball and so is a stellar $(n-1)$ -manifold by induction and, again by the induction, $\text{lk}(B; \text{lk}(v; M))$ is a stellar $(n-s-1)$ -ball or $(n-s-1)$ -sphere. This establishes the induction step for (i).

Suppose that M_1 and M_2 are complexes and $(A; a)M_1 = M_2$. If a vertex v of M_1 is not in $\text{st}(A; M_1)$ then $\text{lk}(v; M_2) = \text{lk}(v; M_1)$. If $v \in \text{lk}(A; M_1)$, then $\text{lk}(v; M_2) = (A; a)\text{lk}(v; M_1)$. Thus the links of v in M_1 and M_2 are related by a stellar move; if one is a stellar ball or sphere, then so is the other. If v is a vertex of A so that $A = v \cup B$, then $\text{lk}(v; M_2)$ is isomorphic to $(B; b)\text{lk}(v; M_1)$ so similar remarks apply. Finally $\text{lk}(a; M_2)$ is $\text{lk}(a; M_1)$. If M_1 is a stellar n -manifold, $\text{lk}(A; M_1)$ is, by (i), a stellar ball or sphere and hence so is $\text{lk}(a; M_2)$. Hence if two manifolds differ by one stellar move and one of them is a stellar n -manifold then so is the other. \square

The boundary ∂M of a stellar n -manifold M is all simplexes that have as link in M a stellar ball. It is not hard to see that this is a subcomplex and is a stellar $(n - 1)$ -manifold without boundary.

If X is a stellar n -ball it follows at once from the definitions that $X \cong \mathbb{D}^n \cong \mathbb{S}^{n-1} \vee \mathbb{D}^n$. However, in a sequence of stellar moves that produces this equivalence many of the moves may be of the form $(A; a)^{-1}$ where $A \subseteq \partial X$. If $A \subseteq \partial X$, $(A; a)$ is called an *internal move*.

Definition 3.3 If X is a stellar n -ball and there is an equivalence $X \cong \mathbb{D}^n$ using only *internal moves*, then X is said to be *starrable* and the sequence of moves is a *starring* of X .

Lemma 3.4 Suppose that a stellar n -ball K can be starred. Then any stellar subdivision L of K can also be starred.

Proof Suppose that $K \xrightarrow{(A;a)} L$. It may be assumed that $A \subseteq \partial K$ for otherwise the result follows trivially. Suppose that $K \cong \mathbb{D}^n$ by r (internal) moves and suppose, inductively that the result is true for any stellar n -ball that can be starred with less than r moves. If $r = 0$ both K and L are cones and there is nothing to prove.

Suppose that the first of the r moves is a stellar subdivision $K \xrightarrow{(B;b)} K_1$. As this is an internal move, $\partial K_1 = \partial K$ and so $A \subseteq \partial K_1$. Let L_1 be the result of starring K_1 at a . It follows from the induction hypothesis that L_1 can be starred.

If there is no simplex in K with both A and B as a face, or if $A \setminus B = \emptyset$, then $L \xrightarrow{(B;b)} L_1$ so it follows at once that L can be starred. Note that essentially the proof here is the assertion $(A;a)(B;b)$ and $(B;b)(A;a)$ both change K to L_1 .

Now suppose that $A \setminus B = C$ for some $C \subseteq K$ and, writing $A = A_0 \cup C$ and $B = B_0 \cup C$, that $A_0 \cup B_0 \cup C \subseteq K$. Compare again the results of the subdivisions $(A;a)(B;b)$ and $(B;b)(A;a)$ on K . The resulting complexes can only differ in the way that the join of $A_0 \cup B_0 \cup C$ to its link is subdivided. Thus consider the effect of $(B;b)(A;a)$ on $A_0 \cup B_0 \cup C$.

$$\begin{aligned} A_0 \cup B_0 \cup C &\xrightarrow{(A;a)} @A \cup a \cup B_0 \\ &= (A_0 \cup @C \cup a \cup B_0) \cup (C \cup @A_0 \cup a \cup B_0) \\ &\xrightarrow{(B;b)} (@A_0 \cup @C \cup a \cup B_0) \cup (@A_0 \cup a \cup b \cup @B) \\ &= (A_0 \cup @C \cup a \cup B_0) \cup (@A_0 \cup a \cup b \cup B_0 \cup @C) \cup (@A_0 \cup a \cup b \cup @B_0 \cup C) \\ &= (@(b \cup A_0) \cup a \cup B_0 \cup @C) \cup (@A_0 \cup a \cup b \cup @B_0 \cup C) : \end{aligned}$$

If d is a point in the interior of $a?B_0$ the stellar subdivision $(a?B_0; d)$ changes this last complex to

$$(@ (b?A_0) ? d ? @ (a?B_0) ? @ C) [(@ A_0 ? a ? b ? @ B_0 ? C);$$

see Figure 2.

Figure 2

This is a symmetric expression with respect to A and B so the subdivision $(b?A_0; d^l)(A; a)(B; b)$, for d^l in the interior of $b?A_0$, produces on $A_0?B_0?C$ an isomorphic result. Taking joins with the link of $A_0?B_0?C$ in K , it follows that $(b?A_0; d^l)L_1$ and $(a?B_0; d)(B; b)L$ are isomorphic. Thus L differs from L_1 by internal moves and so is starrable.

If the first of the r moves is a weld on K that creates K_1 then $K_1 \stackrel{(B; b)}{\cong} K$ for some simplex B in the interior of K_1 . However it has just been shown that then L and L_1 differ by internal moves so, as L_1 is starrable, so is L . \square

Lemma 3.5 *Suppose that a stellar n -ball K can be starred. Then $v?K$, the cone on K with vertex v , can also be starred.*

Proof Suppose that $K = u?(@K)$ by s internal moves and suppose, inductively that the result is true for any stellar n -ball that can be starred with fewer than s moves. If $s = 0$ then $K = u?(@K)$ and $v?u?(@K)$ can be starred by a stellar subdivision at a point in the interior of the 1-simplex $v?u$.

Suppose that the first of the s moves changes K to K_1 by a weld. Then $v?K$ can be obtained from $v?K_1$ by a stellar subdivision. As by induction $v?K_1$ is starrable, it follows from Lemma 3.4 that $v?K$ is starrable.

Thus suppose that, for A in the interior of K , the first of the s moves is $K \stackrel{(A; a)}{\cong} K_1$. Let $P = \text{lk}(A; K)$ and let Q be the closure of $K - \text{st}(A; K)$ so that

$$v?K = v?Q [v?A?P;$$

For b a point in the interior of $v \triangleleft A$,

$$v \triangleleft A \triangleleft P \stackrel{(v \triangleleft A, b)}{\cong} b \triangleleft @ (v \triangleleft A) \triangleleft P = v \triangleleft b \triangleleft @ A \triangleleft P \sqcup b \triangleleft A \triangleleft P$$

Now $(v \triangleleft Q) \sqcup (b \triangleleft v \triangleleft @ A \triangleleft P)$ is a copy of $v \triangleleft K_1$ which is starrable by induction. So for some vertex w

$$v \triangleleft K \cong w \triangleleft v \triangleleft @ K \sqcup Q \sqcup b \triangleleft @ A \triangleleft P \sqcup b \triangleleft A \triangleleft P$$

by internal moves. However, replacing v by w in the above argument,

$$(w \triangleleft b \triangleleft @ A \triangleleft P) \sqcup (b \triangleleft A \triangleleft P) \cong w \triangleleft A \triangleleft P$$

also by internal moves. Hence $v \triangleleft K \cong w \triangleleft @ (v \triangleleft K)$ by internal moves. \square

Theorem 3.6 Any stellar n -ball K can be starred.

Proof Assume inductively that stellar $(n - 1)$ -balls K can always be starred.

Suppose that K is equivalent to \triangleleft^n by r moves and suppose the result is true for any stellar n -ball that is equivalent to \triangleleft^n by fewer than r moves. Suppose that the first of the r moves changes K to K_1 . The induction step follows immediately if this first move is internal and it follows from Lemma 3.4 if the first move is a weld. Thus suppose that $K \stackrel{(A, a)}{\cong} K_1$ where $A \triangleleft @ K$. Express A as $v \triangleleft B$, where v is a vertex of A and B is the opposite face, so that $\text{st}(A; K) = v \triangleleft B \triangleleft \text{lk}(A; K)$. However $B \triangleleft \text{lk}(A; K)$, being a stellar $(n - 1)$ -ball (by Lemma 3.2) is starrable by induction on n , and hence $\text{st}(A; K)$ is starrable by Lemma 3.5. Denoting by X the closure of $K - \text{st}(A; K)$ it follows that, by internal moves,

$$K \cong X \sqcup w \triangleleft @ \text{st}(A; K) = X \sqcup w \triangleleft @ A \triangleleft \text{lk}(A; K) \sqcup A \triangleleft \text{lk}(A; @K) ;$$

But $X \sqcup w \triangleleft @ A \triangleleft \text{lk}(A; K)$ is isomorphic to K_1 and so it is starrable and can thus be changed by internal moves to $x \triangleleft @ X \sqcup w \triangleleft @ A \triangleleft \text{lk}(A; K)$. However,

$$x \triangleleft w \triangleleft @ A \triangleleft \text{lk}(A; @K) \sqcup w \triangleleft A \triangleleft \text{lk}(A; @K)$$

can be changed by one internal weld to $x \triangleleft A \triangleleft \text{lk}(A; @K) = x \triangleleft \text{st}(A; @K)$. Thus $K \cong x \triangleleft @ K$ by internal moves, as required to complete the induction argument. \square

Lemma 3.7 Let M be a stellar n -manifold containing a stellar $(n - 1)$ -ball K in its boundary. Suppose that the cone $v \triangleleft K$ intersects M only in K . Then $v \triangleleft K \sqcup M \cong M$.

Proof By Theorem 3.6 the ball K is starrable. Any stellar subdivision of K extends to a stellar subdivision of M and of $v \in K$. An internal weld on K certainly extends over $v \in K$ and it can be extended over M , after stellar moves, in the following way. Suppose the weld is $K_1 \xrightarrow{(A;a)} K$. Using Theorem 3.6 again, star the stellar n -ball $\text{st}(a; M)$, thus changing M to a stellar equivalent manifold M^0 . This M^0 contains a cone on $\text{st}(a; K)$ which can be used to extend the weld over M^0 . Thus it may be assumed that K is a cone, $x \in K$ say, and (after starring $\text{st}(x; M)$) that M contains a cone, $y \in K$ say, on K . The result then follows from the observation that

$$(v \in x \in K) \cap (y \in x \in K) \quad v \in y \in K = v \in x \in K: \quad \square$$

Theorem 3.8 (Newman [9]) *Suppose S is a stellar n -sphere containing a stellar n -ball K . Then the closure of $S - K$ is a stellar n -ball.*

Proof Inductively assume the theorem is true for all stellar $(n - 1)$ -spheres. This assumption implies that the closure of $S - K$, is a stellar n -manifold; it is used in checking that the link of a vertex in the boundary is indeed a stellar $(n - 1)$ -ball.

As, by Theorem 3.6, K can be starred, it is sufficient to prove the result when K is restricted to being the star of a vertex of S . The sphere S is equivalent to $@^{n+1}$ by a sequence of r stellar moves. Assume inductively that the (restricted) result is true for fewer moves. Suppose that $S \xrightarrow{(A;a)} S_1$ is the first of the r moves and that v is a vertex of S . Let X be the closure of $S - \text{st}(v; S)$ and X_1 be the closure of $S_1 - \text{st}(v; S_1)$. If $v \notin A$ then $X \xrightarrow{(A;a)} X_1$. If $A = v \in B$ for some face B of A , then $X \cap a \in B \in \text{lk}(A; S) = X_1$. Now X is a stellar n -manifold containing the stellar $(n - 1)$ -ball $B \in \text{lk}(A; S)$ in its boundary. Thus by Lemma 3.7 $X = X_1$. However induction on r asserts that X_1 is a stellar n -ball and so X is too.

Suppose the first of the r moves is a weld so that $S_1 \xrightarrow{(A;a)} S$. If $v \neq a$ so that $v \in S_1$, then $X = X_1$, by the same argument as before, and so X is a stellar n -ball. If $v = a$ then X is the closure of $S_1 - \text{st}(A; S_1)$. Let x be any vertex of A , so that $A = x \in B$ say, and let Y_1 be the closure of $S_1 - \text{st}(x; S_1)$. This Y_1 is a stellar n -ball (induction on r) and $@Y_1$ contains the stellar $(n - 1)$ -ball $B \in \text{lk}(A; S_1)$. Let Z be the closure of $@Y_1 - B \in \text{lk}(A; S_1)$, a stellar $(n - 1)$ -ball by the induction on n . Then $X = Y_1 \cap x \in Z$ and so X is a stellar n -ball by Lemma 3.7. □

Theorem 3.9 (Alexander [1]) *Let M be a stellar n -manifold, let J be a stellar n -ball. Suppose that $M \setminus J = @M \setminus @J$ and that this intersection is a stellar $(n - 1)$ -ball K . Then $M \cap J = M$.*

Proof It may be assumed, by Theorem 3.6, that J is a cone, $x \in J$ say. Let L be the closure of $J - K$. Then L is a stellar $(n - 1)$ -ball by Theorem 3.8 and so can be starred (by Theorem 3.6) to become $y \in L = y \in K$; the stellar equivalence of this starring extends over the cone $x \in L$ to give $x \in L \iff x \in y \in L = y \in x \in K$. Thus

$$M \setminus J \iff M \setminus [x \in K \setminus y \in x \in K]$$

and this is equivalent to M by two applications of Lemma 3.7. \square

4 Arbitrary subdivision

This section connects the idea, just discussed, of stellar moves with that of arbitrary subdivision and, in so doing, equates stellar manifolds with combinatorial manifolds. Here it really does help to have simplicial complexes contained in some \mathbb{R}^N . In order to consider arbitrary subdivisions of simplicial complexes it will be convenient to consider the idea of a convex linear cell complex, a generalisation of the idea of a simplicial complex. In principle this is needed because, if K_1 and K_2 are simplicial complexes in \mathbb{R}^N , there is no natural simplicial triangulation for $jK_1j \setminus jK_2j$. Any $(n - 1)$ -dimensional affine subspace (or *hyperplane*) \mathbb{R}^{N-1} of \mathbb{R}^N separates \mathbb{R}^N into two closed half spaces \mathbb{R}_+^N and \mathbb{R}_-^N . A convex linear cell (sometimes called a polytope) in \mathbb{R}^N is a *compact* subset that is the intersection of finitely many such half spaces. A face of the cell is the intersection of the cell and any subset of the hyperplanes that define these half spaces; the proper faces constitute the boundary of the cell. The dimension of the cell is the smallest dimension of an affine subspace that contains the cell. A convex linear cell complex C in \mathbb{R}^N is then defined in the same way as is a finite simplicial complex but using convex linear cells in place of simplexes. In the same way the underlying polyhedron jCj and the idea of a subdivision of one convex linear cell complex by another are defined. Note that any convex linear cell complex has a subdivision that is a simplicial complex; an example of a simplicial subdivision is a first derived subdivision, one that subdivides cells in some order of increasing dimension, each as a cone on its subdivided boundary.

Definition 4.1 Two convex linear cell complexes are piecewise linearly homeomorphic if they have simplicial subdivisions that are isomorphic.

It is easy to see that if there is a face-preserving bijection between the cells of one convex linear cell complex and those of another, then the complexes are piecewise linearly homeomorphic.

Lemma 4.2 *Let A be a convex linear n -cell and let \mathcal{A} be any subdivision of its boundary. Then \mathcal{A} is piecewise linearly isomorphic to \mathcal{S}^n .*

Proof Choose \mathcal{S}^n to be contained (linearly) in A and let v be a point in the interior of \mathcal{S}^n . Let $\{B_i\}$ be the cells of \mathcal{A} and $\{C_j\}$ be the simplexes of \mathcal{S}^n . Let $D_{i,j} = (v \cap B_i) \cap C_j$. Then $\{D_{i,j}\}$ forms a convex linear cell complex subdividing \mathcal{S}^n . Let \mathcal{S}'^n be a simplicial subdivision of this cell complex. Projecting, radially from v , the simplexes of \mathcal{S}'^n produces a simplicial subdivision \mathcal{A}' of \mathcal{A} and the radial correspondence gives the required bijection between the simplexes of \mathcal{S}^n and \mathcal{A} (though such a projection is not linear when restricted to an actual simplex). \square

Corollary 4.3 *Any subdivision of a convex linear n -cell is piecewise linearly isomorphic to \mathcal{S}^n .*

Proof Let \mathcal{A} be a subdivision of a convex linear n -cell A . As above, $\mathcal{S}'^n \cap A$ is a simplicial complex isomorphic to the subdivision \mathcal{S}'^n of \mathcal{S}^n . The intersection of the simplexes of $\mathcal{S}'^n \cap A$ with the cells of \mathcal{A} gives a common cell-subdivision of these two complexes. \square

The aim of what follows in Theorem 4.5 is to prove the fact that any simplicial subdivision of a simplicial complex K is stellar equivalent to K . The next lemma is a weak form of this.

Lemma 4.4 *Let K be an n -dimensional simplicial complex and let \mathcal{K} be a simplicial subdivision of K with the property that, for each simplex A in K , the subdivision $\mathcal{K} \cap A$ is a stellar ball. Then $\mathcal{K} \sim K$.*

Proof Let \mathcal{K}_r be the subdivision of K such that, if $A \in K$ and $\dim A = r$, then $\mathcal{K}_r \cap A = A$ and if $\dim A > r$ then A is subdivided as the cone on the already defined subdivision of its boundary (think of the simplexes being subdivided one by one in some order of increasing dimension). If $A \in K$ and $\dim A = r$ then the stellar r -ball $\mathcal{K}_r \cap A$ can be starred. As this is an equivalence by internal moves, simplexes of dimension less than r are unchanged, and the stellar moves can be extended conewise over the subdivided simplexes of higher dimension. In this way, $\mathcal{K}_r \sim \mathcal{K}_{r-1}$. However $\mathcal{K}_n = K$ and \mathcal{K}_0 is just a first derived subdivision of K which is certainly stellar equivalent to K . \square

The next theorem is the promised result that links arbitrary subdivisions with stellar moves. It is an easy exercise to produce a subdivision of \mathbb{R}^2 that is not the result of a sequence of stellar subdivisions on \mathbb{R}^2 . It is a classic conjecture, which the author believes to be still unsolved, that if two complexes are piecewise linearly homeomorphic (that is, they have isomorphic subdivisions) then they have isomorphic subdivisions each obtained by a sequence of stellar subdivisions (with no welds being used).

Theorem 4.5 *Two n -dimensional simplicial complexes are piecewise linearly homeomorphic if and only if they are stellar equivalent.*

Proof Clearly, stellar equivalent complexes are piecewise linearly homeomorphic. Thus it is sufficient to prove that if K is a simplicial subdivision of any n -dimensional simplicial complex K , then $K \sim K$. Assume inductively that this is true for all simplicial complexes of dimension less than n .

Suppose that C is a convex linear cell complex contained in \mathbb{R}^N , that \mathbb{R}^{N-1} is an affine $(N-1)$ -dimensional subspace of \mathbb{R}^N and that \mathbb{R}_+^N and \mathbb{R}_-^N are the closures of the complementary domains of \mathbb{R}^{N-1} . The *slice of C by \mathbb{R}^{N-1}* is defined to be the convex linear cell complex consisting of all cells of one of the forms $A \cap \mathbb{R}_+^N$, $A \cap \mathbb{R}_-^N$ or $A \cap \mathbb{R}^{N-1}$ where A is a cell of C . An r -slice subdivision of C is the result of a sequence of r slicings by such affine subspaces of dimension $(N-1)$. Let K be an n -dimensional simplicial complex and suppose C_r is an r -slice subdivision of K . Let \mathcal{C}_r be any simplicial subdivision of C_r such that each top dimensional (n -dimensional) cell is subdivided as a cone on the subdivision of its boundary. Suppose inductively that for smaller r any such \mathcal{C}_r is stellar equivalent to K .

To start the induction, when $r = 0$, it is necessary to consider a simplicial subdivision \mathcal{C}_0 of K in which all the n -simplexes of K are subdivided as cones on their boundaries. If $A \supseteq K$ and $\dim A < n$ then A is, by the induction on n , a stellar ball. If $\dim A = n$, then A is a cone on ∂A . But ∂A is, by the induction on n , a stellar $(n-1)$ -sphere and so the cone A is a stellar n -ball. Thus in \mathcal{C}_0 the subdivision of every simplex of K is a stellar ball and so, by Lemma 4.4, $\mathcal{C}_0 \sim K$.

Suppose that the r -slice subdivision C_r of K is obtained by slicing the $(r-1)$ -slice subdivision C_{r-1} . Choose a simplicial subdivision \mathcal{C}_{r-1} of C_{r-1} so that, on the cells of dimension less than n , \mathcal{C}_{r-1} is the slicing by the r^{th} affine subspace \mathbb{R}^{N-1} followed by \mathcal{C}_{r-1} . On an n -cell, \mathcal{C}_{r-1} is a subdivision of the cell as the cone on its subdivided boundary. The induction on r implies that $\mathcal{C}_{r-1} \sim K$. Thus, to complete the induction it is necessary to show that $\mathcal{C}_r \sim \mathcal{C}_{r-1}$. Now

C_{r-1} and C_r differ only in the way that the interiors of the n -cells of C_{r-1} are subdivided. Suppose that A is an n -cell of C_{r-1} and that $A \setminus \mathbb{R}^{N-1}$ is an $(n-1)$ -cell. Thus in C_r , the cell A is divided into two cells, X and Y say, intersecting in the cell $A \setminus \mathbb{R}^{N-1}$ contained in their boundaries. Now ∂X is, by induction on n and Lemma 4.2, a stellar $(n-1)$ -sphere and so X , which is the cone on this, is a stellar n -ball. Similarly Y is a stellar n -ball. Again by induction on n and using Corollary 4.3, $(A \setminus \mathbb{R}^{N-1})$ is a stellar $(n-1)$ -ball. Thus by Theorem 3.9 $X \cup Y$ is a stellar n -ball and so, by Theorem 3.6 can be starred by internal moves. This starring process changes A to A . Repetition of this on every n -cell of C_{r-1} shows that $C_{r-1} \approx C_r$. That completes the proof of the induction on r .

Figure 3

Finally, consider the simplicial subdivision K of the n dimensional simplicial complex K assumed to be contained in some \mathbb{R}^N . For each simplex A of K (of dimension less than N) choose an affine subspace \mathbb{R}^{N-1} containing A but otherwise in general position with respect to all the vertices of K . Using all these affine subspaces, construct an r -slice subdivision C of K . Suppose $A \in K$ is a p -simplex contained in a p -simplex B of K . The above general position requirement ensures that B meets the copy of \mathbb{R}^{N-1} , selected to contain any $(p-1)$ -dimensional face of A , in the intersection of B with the $(p-1)$ -dimensional affine subspace containing that face (and not in the whole of B). Thus the slice subdivision of K using just these particular $p+1$ hyperplanes contains the simplex A as a cell. Of course, A is subdivided if more of the slicing operations are used, but this means that C is also an r -slice subdivision of K . Let σ be a simplicial subdivision of C as described above. Then by the above $K \approx C \approx K$. □

In the light of the preceding theorem, combinatorial balls, spheres and manifolds are the same as the stellar balls, spheres and manifolds previously considered. Thus in all the preceding results of section 3, the word ‘combinatorial’ can now replace ‘stellar’. In the rest of this paper the ‘combinatorial’ terminology will be used. It is worth remarking that in [10] Newman modifies Theorem 3.6 so that he can improve Theorem 4.5 by restricting the needed elementary stellar subdivisions and welds to those involving only 1-simplices.

As in Lemma 3.2, it follows that the link of any r -simplex in M is a combinatorial $(n - r - 1)$ -ball or sphere. The following is a short technical lemma concerning this that will be used later.

Lemma 4.6 *Suppose that B is an r -simplex, that X is any simplicial complex and $@B \text{ ? } X$ is a combinatorial n -sphere or n -ball. Then X is a combinatorial $(n - r)$ -sphere or $(n - r)$ -ball.*

Proof For v a new vertex, $v \text{ ? } @B \text{ ? } X$ is a combinatorial $(n + 1)$ -ball. But this is piecewise linearly homeomorphic to $B \text{ ? } X$. Thus $\text{lk}(B; B \text{ ? } X)$, namely X , is a combinatorial $(n - r)$ -sphere or $(n - r)$ -ball. \square

5 Moves on manifolds

This section deduces that bistellar moves suffice to change one triangulation of a closed piecewise linear manifold to another. A similar theorem for bounded manifolds is also included. A version of the proof of Pachner [11], [12], is employed. Firstly there follow definitions of some relations between combinatorial n -manifolds. They are best thought of as more types of ‘moves’ changing one complex to another within the same piecewise linear homeomorphism class.

Definition 5.1 Let A be a non-empty simplex in a combinatorial n -manifold M such that $\text{lk}(A; M) = @B \text{ ? } L$ for some simplex B with $; \notin B \cong M$ and some complex L . Then M is related to M^0 by the stellar exchange $(A; B)$, written $M \xrightarrow{(A; B)} M^0$, if M^0 is obtained by removing $A \text{ ? } @B \text{ ? } L$ from M and inserting $@A \text{ ? } B \text{ ? } L$.

Figure 4

This idea is illustrated in Figure 4. If $L = \cup$, then $(A; B)$ is, as defined in Section 2, a bistellar move. As in Section 2, for this definition and for others like it, it is best to consider M as an abstract simplicial complex. Otherwise, topologically, ' $B \not\cong M$ ' should here be expanded to mean that $A \not\cong B \not\cong L$ exists and meets M only in $A \not\cong B \not\cong L$. It is important here not to be deterred by a feeling that the existence of simplexes such as A is rather unlikely. Note that $M^0 \xrightarrow{(B;A)} M$ is the inverse move to $(A; B)$. If B is a single vertex a , so that $\partial B = \{a\}$, then $(A; B)$ is the stellar subdivision $(A; a)$ discussed at length in Section 3. Note that any $(A; B)$ is the composition of a stellar subdivision and a weld, namely $(B; a)^{-1}(A; a)$.

Definition 5.2 Suppose that A and B are simplexes of a combinatorial n -manifold M with boundary ∂M , that the join $A \not\cong B$ is an n -simplex of M , that $A \setminus \partial M = \partial A$ and $B \not\cong \partial A \subset \partial M$. The manifold M^0 obtained from M by elementary shelling from B is the closure of $M - (A \not\cong B)$.

Here taking the closure means adding on the smallest number of simplexes (in this case those of $A \not\cong B$) to achieve a simplicial complex. The relation between M and M^0 will be denoted $M \xrightarrow{(\text{sh } B)} M^0$. Note that ∂M^0 and ∂M are related by a bistellar move.

Definition 5.3 A combinatorial n -ball is shellable if it can be reduced to a single n -simplex by a sequence of elementary shellings. A combinatorial n -sphere is shellable if removing some n -simplex from it produces a shellable combinatorial n -ball.

Note that there are well known examples of combinatorial n -spheres and combinatorial n -balls that are *not* shellable (see, for example, [14], [3] or [7]). For future use, three straightforward lemmas concerning shellability now follow.

Lemma 5.4 *If X is a shellable combinatorial n -ball or n -sphere then the cone $v \not\cong X$ is shellable.*

Proof If X is a combinatorial n -ball, for every elementary shelling $(\text{sh } B)$ in a shelling sequence for X , perform the shelling $(\text{sh } B)$ on $v \not\cong X$ (with $v \not\cong A$ in place of A). This shows that $v \not\cong X$ is shellable. Suppose then that X is a combinatorial n -sphere and $X - C$ is a shellable ball for some n -simplex C . Then $v \not\cong X \xrightarrow{(\text{sh } C)} v \not\cong (X - C)$ and the result follows from the preceding case. \square

Lemma 5.5 *If X is a shellable combinatorial n -ball or n -sphere then $@^r X$ is shellable.*

Proof Suppose X is a combinatorial n -ball. Work by induction on r ; when $r = 0$ there is nothing to prove. Write $^r = v \triangleleft C$ for some vertex v and $(r - 1)$ -simplex C . Suppose that the shellings $(sh B_1); (sh B_2); \dots; (sh B_s)$ on X change X to a single n -simplex. Then shellings $(sh (C \triangleleft B_1)); (sh (C \triangleleft B_2)); \dots; (sh (C \triangleleft B_s))$ followed by $(sh C)$ change $@^r X$ to $v \triangleleft @C \triangleleft X$ and the result follows by induction on r and the last lemma. Now let X be a combinatorial n -sphere with $X - D$ shellable for some n -simplex D . Suppose that $@C$ can be reduced to a single $(r - 2)$ -simplex by the removal of an $(r - 2)$ -simplex C_0 followed by shellings $(sh C_1); (sh C_2); \dots; (sh C_t)$. Then shellings $(sh (D \triangleleft C_0)); (sh (D \triangleleft C_1)); \dots; (sh (D \triangleleft C_t))$ followed by $(sh D)$ change $@(v \triangleleft C) \triangleleft X - C \triangleleft D$ to $@(v \triangleleft C) \triangleleft (X - D)$ which is shellable by the previous case. \square

Definition 5.6 Combinatorial n -manifolds M_1 and M_2 are bistellar equivalent, written $M_1 \sim M_2$, if they are related by a sequence of bistellar moves and simplicial isomorphisms.

Lemma 5.7 *If X is a shellable combinatorial n -ball, then the cone $v \triangleleft @X$ is shellable.*

Proof The proof is by induction on the number, r , of n -simplexes in X . If $r = 1$ a single starring of the simplex X produces $v \triangleleft @X$. Suppose that the first elementary shelling of X is $X \xrightarrow{(sh A \triangleleft B)} X_1$, where $A \triangleleft B$ is an n -simplex of X , $A \setminus @X = @A$ and $B \triangleleft @A \triangleleft @X$. By the induction on r , $X_1 \sim v \triangleleft @X_1$. However, $v \triangleleft @X_1 [A \triangleleft B$ is changed to $v \triangleleft @X$ by the bistellar move $(A; v \triangleleft B)$. \square

Corollary 5.8 *Let M be a combinatorial n -manifold, let $A \triangleleft (M - @M)$ and suppose that $lk(A; M)$ is shellable. Then $M \sim (A; a)M$ for a a vertex not in M .*

Proof Iteration of Lemma 5.4 shows that $A \triangleleft lk(A; M)$ is shellable and so Lemma 5.7 implies that $A \triangleleft lk(A; M)$ is bistellar equivalent to the cone on its boundary. However this cone is $a \triangleleft @A \triangleleft lk(A; M)$. \square

Theorem 5.9 (Newman [9], Pachner [11], [12]) *Two closed combinatorial n -manifolds are piecewise linearly homeomorphic if and only if they are bistellar equivalent.*

Proof By Theorem 4.5 it is sufficient to prove that, if closed combinatorial n -manifolds M and M^0 are related by a stellar exchange, then they are bistellar equivalent. Thus suppose that $\text{lk}(A; M) = @B ? L$ and suppose $M \xrightarrow{(A;B)} M^0$. Suppose that L can be expressed as $L = L^0 ? S$ where S is some join of copies of $@^p$ for any assorted values of p (though S could well be empty). By Lemma 4.6, L and L^0 are (possibly empty) combinatorial spheres. Let $\dim L^0 = m$. As L^0 is a stellar m -sphere it is related to $@^{m+1}$ by a sequence of r , say, stellar moves. The proof proceeds by induction on the pair $(m; r)$, assuming the result is true for smaller m , or the same m but smaller r , smaller than is than the values under consideration. Note that if $m = 0$ the 0-sphere L^0 can be absorbed into S . For any value of m , if $r = 0$ then L^0 is a copy of $@^{m+1}$ and can again be absorbed into S .

However, if L^0 is empty ($m = -1$), then L is shellable (by Lemma 5.5) and so (again using Lemma 5.5) $\text{lk}(A; M)$ and $\text{lk}(B; M^0)$ are both shellable. Thus, by Corollary 5.8,

$$M \xrightarrow{(A;a)} M = (B;a)M^0 \xrightarrow{} M^0.$$

These remarks start the induction.

Suppose that the first of the r moves that relate L^0 to $@^{m+1}$ is the stellar exchange $(C; D)$ (it is convenient to use the stellar exchange idea to avoid distinguishing subdivisions and welds). Thus $C \supseteq L^0$ and $\text{lk}(C; L^0) = @D ? L^0$ for some complex L^0 .

There are two cases to consider, the first being when $D \not\supseteq M$. Consider the combinatorial manifolds M_1 and M_2 obtained from M in the following way

$$M \xrightarrow{(A?C;D)} M_1 \xrightarrow{(A;B)} M_2.$$

Because $\text{lk}(A ? C; M) = @B ? S ? @D ? L^0$ and $\dim L^0 < m$, it follows by induction on m (regarding $@B ? S$ as the 'new S ') that $M \xrightarrow{} M_1$. Because $\text{lk}(A; M_1) = @B ? S ? (C; D)L^0$ it follows that $M_1 \xrightarrow{} M_2$ by induction on r .

The same M_2 can also be achieved in an alternative manner:

$$M \xrightarrow{(A;B)} M^0 \xrightarrow{(B?C;D)} M_2.$$

That this is indeed the same M_2 can be inferred from considerations of the symmetry between A and B , but it is also easy to check that $A ? C ? @B ? @D ? S ? L^0$ is changed by each pair of moves to

$$(B ? D ? @A ? @C) [(C ? D ? @A ? @B) ? S ? L^0$$

and clearly the changes produced on the rest of M are the same. However, $\text{lk}(B ? C; M^0) = @A ? S ? @D ? L^0$ so, here again by induction on m , $M^0 \xrightarrow{} M_2$. Hence $M \xrightarrow{} M^0$.

The second case is when $D \geq 2$. A trick reduces this to the first case in the following way. It may be assumed that $\dim D = 1$ because if D is just a vertex an alternative new vertex can be used instead. Write $D = u \cup E$ for u a vertex and E the opposite face in D . Let v be a new vertex not in M . Consider the manifold M^0 obtained by

$$M \xrightarrow{(A;u,v)} \hat{M} \xrightarrow{(A;B)} \hat{M}^0$$

or obtained alternatively, as seen by symmetry considerations, by

$$M \xrightarrow{(A;B)} M^0 \xrightarrow{(B;u,v)} \hat{M}^0.$$

Because $\text{lk}(A; \hat{M}) = @B \cup (u;v)L^0 \cup S$ and $(u;v)L^0$ is just a copy of L^0 with v replacing u , it follows by the first case that $\hat{M} \cong \hat{M}^0$. However, because $\text{lk}(A; u; M) = @B \cup \text{lk}(u; L^0) \cup S$, the induction on m gives $M \cong \hat{M}$. Similarly $M^0 \cong \hat{M}^0$. Hence it follows again that $M \cong M^0$. \square

An elegant version for bounded manifolds, of this last result, will now be discussed. The proof again is based on Pachner's work. Only an outline of the proof, which runs along the same lines as that of Theorem 5.9, will be given here. An obvious extension of terminology will be used. If the manifold M^0 is obtained from M by an elementary shelling then M will be said to be obtained from M^0 by an elementary inverse shelling.

Theorem 5.10 (Newman [9], Pachner [12]) *Two connected combinatorial n -manifolds with non-empty boundary are piecewise linearly homeomorphic if and only if they are related by a sequence of elementary shellings, inverse shellings and a simplicial isomorphism.*

Outline proof Suppose M is a connected combinatorial n -manifold with $@M \neq \emptyset$. Firstly, note in the following way that a bistellar move on M can be expressed as a sequence of elementary shellings and inverse shellings. In such a bistellar move $(A;B)$, the simplex A is in the interior of M because $\text{lk}(A; M) = @B$. Find a chain of n -simplexes, each meeting the next in an $(n-1)$ -face, that connects $\text{st}(A; M)$ to an $(n-1)$ -simplex F in $@M$ (see Figure 5(i)). By a careful use of inverse shellings, add to the closure of $@M - F$ a collar, a copy of $(@M - F) \times I$, see Figure 5(ii). Then, by elementary shellings of the union of M and this collar, remove all the n -simplexes of the chain together with $\text{st}(A; M)$. Next, using inverse elementary shellings, replace $\text{st}(A; M)$ with $B \cup @A$ and reinsert the chain of n -simplexes. Finally remove the collar by elementary shellings. The use of the collar ensures that the chain of n -simplexes, which might meet $@M$ in an awkward manner, can indeed be removed by shellings.

Figure 5

In the light of this last remark and Theorem 4.5, it is sufficient to prove that, if $M \xrightarrow{(A;B)} M^0$ is a stellar exchange, then M and M^0 are related by a sequence of elementary shellings and inverse shellings and bistellar moves. Proceed as in the proof of Theorem 5.9. If A is in the interior of M , then M and M^0 are related by a sequence of bistellar moves exactly as in the proof of Theorem 5.9. If however $A \in \partial M$ then the proof must be adapted in the following way.

Suppose that $(A;B)$ is a stellar exchange, where $A \in \partial M$ and $\text{lk}(A;M) = \partial B \# L$. As $\partial B \# L$ is a combinatorial ball it follows from Lemma 4.6 that L is a combinatorial ball and $\partial B \in \partial M$. Thus $A \# \partial B \# \partial L \in \partial M$. Express L as $L = L^0 \# S$ where S is some join of copies of ∂^p for any assorted values of p and possibly some ∂^q . Lemma 4.6 shows that this L^0 is a combinatorial sphere or ball. Note that S and ∂S are shellable. Let $\dim L^0 = m$ and suppose that L^0 is equivalent to ∂^m or ∂^{m+1} by way of r stellar moves. If $m = 0$ or $r = 0$, then L^0 can be incorporated into S thus reducing L^0 to the empty set.

If $L^0 = \partial^m$, whether S is a sphere or a ball, the ball L and its boundary are both shellable. In this circumstance the theorem will be established below, and that is the start of the inductive proof on the pair $(m;r)$. Continue then as in the proof of Theorem 5.9. in which $(C;D)$ is a stellar exchange on L^0 , being the first of the above mentioned r moves. The proof proceeds exactly as before except that, if C is in the interior of L^0 , then $A \# C$ and $B \# C$ are in the interior of M and so the stellar exchanges $(A \# C;D)$ and $(B \# C;D)$ are already known to be expressible as a sequence of bistellar moves.

Finally, for the start of the induction, consider the situation when $A \in \partial M$ and L and ∂L , and hence both of $\text{lk}(A;M)$ and $\partial \text{lk}(A;M) = \text{lk}(A;\partial M)$, are shellable. This means (by Lemma 5.4) that $\text{st}(A;\partial M)$ is shellable and, using this, it is straightforward to add to M a cone on $\text{st}(A;\partial M)$ by means of a sequence of elementary inverse shellings. Let the resulting manifold be M_+ (see Figure 6) so that $M_+ = (v \# \text{st}(A;\partial M)) \# M$ where v is a new vertex.

For brevity let $X = \text{lk}(A;M)$. Suppose that the first elementary shelling, in a shelling sequence for X , changes X to X_1 by the removal of a simplex $E \# F$,

Figure 6

where $F \setminus @X = @F$ $(E \ ? F) \setminus @X = E \ ? @F$. Observe that

$$\text{lk}(A \ ? E; M_+) = F \ [(v \ ? @F) = @(v \ ? F):$$

Thus a stellar exchange $(A \ ? E; v \ ? F)$ can be performed on M_+ which has the effect of removing $\text{st}(A \ ? E; M_+)$ and replacing it with

$$v \ ? F \ ? @ (A \ ? E) = v \ ? F \ ? (@A \ ? E) \ [(A \ ? @E) = (v \ ? A \ ? @E \ ? F) \ [(v \ ? @A \ ? E \ ? F):$$

The second term is the join of $v \ ? @A$ to the simplex removed from X to create X_1 ; the first term is the cone from v on A joined to $@X_1 - @X$. This process can now be repeated by using the remaining elementary shellings that change X_1 to a single simplex and then by using the removal of that final simplex as one last 'elementary shelling'. The result is that M_+ is bistellar equivalent to

$$(M - \text{st}(A; M)) \ [(v \ ? @A \ ? X) = (A; v)M:$$

As previously remarked, if M and M^0 are related by the stellar exchange $M \xrightarrow{(A;B)} M^0$, then $(A; v)M = (B; v)M^0$. Of course, $\text{lk}(B; M^0) = @A \ ? L$. Thus as $(A; v)$ and, similarly, $(B; v)$ have been shown to be expressible as a sequence of elementary shellings, inverse shellings and bistellar moves, the combinatorial manifolds M and M^0 are related by such moves. \square

The results of Theorems 5.9 and 5.10 have a simple memorable elegance, albeit the proofs here given have, at times, been a little involved. It is hoped that publicising these results, together with their proofs, will enable them to find new applications based on confidence in their veracity.
